Sirs,—By a Gazette published on May 14th the number of Greenwich Hospital pensions for fleet and staff surgeons R.N. was reduced to 13; two years ago there were 16, and at this rate of reduction there will soon be none at all; but nobody appears to protest against this spoliation, nobody seems to know and nobody seems to care. Again, with regard to honours the same thing is apparent—there is one C.B. on Active List, made in June, 1902, and since then none have been given to the department. As regards service ceremonial entertainments (certainly at Portsmouth) medical officers and their families are simply never invited—they are not recognised! This contemptuous indifference, increasing for several years past, went so far that two years ago the Sea Lords in the yacht *Enchantress* placed the senior medical officer at Portsmouth at the foot of the table, and though this was apologised for yet the spirit of the thing is very evident. Of course, the present feeling of the Admiralty is to do away with the medical department as far as possible and run the service with temporary medical officers afloat and civilian practitioners ashore; in fact the permanent medical officers are a disagreeable necessity and this in the face of all the good and zealous work that has been done by naval medical officers of recent years. It is pleasing to know that there are some signs of wear and tear on the patience and good will of the naval medical donkey, and he surely will be no better off till he bestirs *himself*, as he has had to do on former occasions. Will you, Sirs, aid us with your influence and permit one of them to

May 22nd, 1907. "Bray."

THE FOUNDATION OF QUEEN'S COLLEGE BIRMINGHAM.

To the Editors of The Lancet.

Sirs,—In the interesting paragraph from your Birmingham Correspondent on the above subject published in The Lancet of May 18th it is stated that a Royal Charter was granted to the institution in the year 1845. Although I know that other speakers and writers on the history of the College have stated the year as 1845 it seems to me, from the account published in The Lancet of July 29th, 1843, that the Charter must have been granted in 1843. That account, which was addressed to The Lancet by Mr. William Sands Cox, states that "Her Majesty has been graciously pleased to grant a Royal Charter of Incorporation to the School of Medicine and Surgery at Birmingham, with the privileges, immunities, rank, and title of the 'Queen's College, Birmingham.'" I am, Sirs, yours faithfully,

May 21st, 1907. W.

Royal Institution.—On Tuesday next (May 28th) at 3 o'clock Professor G H. F. Nuttall will deliver the first of two lectures at the Royal Institution on Malaria, Sleeping Sickness, Tick Fever, and Allied Diseases, and on Saturday, June 1st, Sir William White will begin a course of two lectures on the Contest between Guns and Armour. The Friday evening discourse on June 7th will be delivered by Professor Sir James Dewar on Studies in High Vacua and Helium at Low Temperatures.

THE BATTLE OF THE CLUBS.

The Struggle against the Coventry Dispensary.

(From our Special Commissioner.)

Coventry, May 20th.

The contest at Coventry has now reached the acutest stage and the battle of the clubs is being fought out to the bitter end. It is no longer a question of negotiations, of compromise, of attempts at conciliation. It is open, uncompromising war. Negotiations have been protracted for more than a year, concessions were made on both sides, indeed, the desire to avoid an open rupture has perhaps led each side to infer that the other side feared to fight. To the profession at large it must be a matter of great satisfaction to know that the staff of the Coventry Dispensary have at last fallen into line in the effort made throughout the country to reform the whole system of contract work. Ten years ago[1] I called on some members of the medical staff of the Coventry Provident Dispensary and they readily admitted the existence of many abuses, but it was not possible to persuade them that any results could be gained by resistance. Now, on the contrary, they have been so persuaded, and this is a telling demonstration of the better organisation of the profession. In 1897 they informed me that to their personal knowledge there were 15 medical practitioners at Birmingham ready to come to Coventry if invited by the dispensary. To-day the dispensary has thrown out such invitation broadcast and 21 applications have been made not from Birmingham but from all parts of the kingdom. Ten years ago the members of the dispensary staff argued that if they resigned they would lose the greater part of their income, that there was no sort of guarantee that the profession would really support them, and that there was no prospect of any sort of compensation. To-day they have resigned and in doing so run the risk of losing more than £2000 annually. Surely this is a remarkable change of attitude and it can only be explained by one single fact—namely, the better organisation of the profession. But this must not be allowed to remain an empty boast. The profession, now better organised, must prove that it is capable of effective action.

In view of such action I will leave the consideration of the history and development of the struggle aside for the time being, so as to deal at once with what, in the present emergency, must be done. First and foremost, all petty bickering and criticism and fault-finding must be set aside while the battle is proceeding. Certainly the members of the medical staff attached to the Coventry Provident Dispensary have laid themselves open to criticism on the part of the organised members of the profession who for many long years endeavoured to abate the abuses arising from contract work. The former, on their side, and now that they have joined in the struggle, doubtless also fancy that they have some cause to complain, and notably that more might be done for them by their new allies. All such weakening divisions within the ranks must be sternly kept in abeyance, at least till the struggle is over. Whatever may have been their timidity in the past the medical staff of the dispensary now realise that the position has changed. In the Coventry district there are 42 medical practitioners and one dentist who is a fully-qualified medical man. Of these 41 belong to the Coventry division of the British Medical Association and 11 are officers of the Coventry Public Medical Service which was started by the profession in opposition to the Coventry Provident Dispensary. In these circumstances the members of the medical staff of the latter institution who have resigned have nothing to fear from the practitioners of Coventry. The staff consisted of seven practitioners. Two out of the seven have not resigned; but there is no resentment felt against one of these two as he is over 80 years of age and could not at that age be expected to sacrifice the greater part of his income and to begin life anew. The other medical officer who has not resigned never made much from the dispensary as he had a comparatively small number of members on his books. Thus the strike may be said to have crippled the dispensary completely. Their only chance therefore rests on their ability to import medical officers from the outside. But in this regard what used to be a great advantage to the dispensary will prove of special disadvantage. It so happened that the medical staff comprised some of the best practitioners of Coventry, gentlemen who held high social positions and had among their private patients some of the best families of the neighbourhood. Now, this is a description which does not necessarily apply to the sort of practitioner likely to respond to the appeal of an institution which is condemned by the profession. If the Coventry Dispensary is as unlucky as several other clubs have been the members will feel the contrast all the more as they have been accustomed to a high class of medical attendant.

---

[1] See The Lancet, June 12th (p. 1637) and 19th (p. 1709), 1897.

The Coventry Provident Dispensary has just appointed three outsiders. Two are stated as coming from London; the third has been in Coventry for a few weeks, has not called on anyone, and is unknown to the profession locally. It is more than probable that these three practitioners do not understand their position; and when they do they may probably follow the example of some of their predecessors by promptly resigning. Altogether, it appears there were 21 applicants, including a lady doctor. The latter, it was stated, was going to be appointed, but when she discovered what was the true situation she very properly and loyally adhered to the discipline established by the profession and withdrew her candidature. Now, of course, the first endeavour must be to make the three selected candidates understand the mistake which they have committed in accepting service under the Coventry Provident Dispensary. Of course, no medical practitioner will entertain any sort of relation with them and all will refuse to meet them in consultation. But in days gone by and when the profession was not so well organised consultants came down in similar circumstances from Birmingham and thus defeated the endeavours of the local consultants. To-day this is not likely to occur.

On May 10th the central division, Birmingham branch, of the British Medical Association was convoked to discuss the Coventry dispute. The meeting was largely attended; it is said to have been the most crowded meeting that this organisation has ever held and the following resolution was unanimously adopted:—

> That this division agrees to support the Coventry division in its resolution of April 3rd, 1906, in declaring that no member of the profession in the area of the division should associate himself with the Coventry Provident Dispensary so long as that institution is managed on lines fundamentally different from those laid down for provident dispensaries by the recommendations of the medico-political committee[2] and further declares that after June 24th next, in the event of the rules of management of the dispensary not being altered in a manner satisfactory to the Coventry division, no member of the profession in the area of this division shall meet in consultation or otherwise professionally recognise the members of the medical staff of the dispensary.

In view of this resolution it may be said with confidence that if the members of the Coventry Provident Dispensary have need of a second opinion no consultant either of Coventry or Birmingham will see them unless they dismiss the medical attendants appointed by the dispensary. But many of these possible patients are leaving the dispensary and following the medical officers who have resigned. This course must be encouraged by every means. When the three imported medical officers see how much they have set themselves up against their profession the probabilities are that they will reconsider their position and, in their turn, send in their resignations. But it would be well not to rely too much on this and if their sense of what is due to their own dignity and to their calling cannot be moved perhaps the fact that the members are falling away from the dispensary will affect them more. Thus the general public may ultimately decide the matter. It is, therefore, most urgent that the general public should be well informed as to the points at issue. The Coventry division of the British Medical Association might publish a manifesto to the general public pointing out that club practice such as that of the Coventry Dispensary must degrade the medical profession and thus injure the public at large. The health of the entire community depends to a considerable extent on the medical profession and therefore any sweating of medical men, any system entailing so much overwork as to prevent their studying and following the progress of medicine, must prove to the disadvantage of the patients. The whole of the arguments in so far as the welfare of the general public is concerned should be set forth so that the members of the Coventry Dispensary may be made to understand that their true interest is on the side of the profession and not on the side of an institution which is so organised as to bring about the sweating of its medical officers. It is impossible for any one medical officer to have 5000 or 6000 members on his books and to attend to them properly. This is just what has happened at Coventry and it is degrading to the profession and injurious to the public. The public unfortunately does not fully realise this aspect of the case and therefore information on the question must be spread broadcast. Not only must medical men be warned to keep away from the Coventry Provident Dispensary but the people, that is, the inhabitants of Coventry, must be shown that they must also keep away from this institution and support the organised medical profession, for the interests of the profession and of the public are, at least on this question, absolutely identical.

(To be continued.)

SOME EFFECTS OF THE EMPLOYERS' LIABILITY ACT.

(From a Correspondent.)

There is no question that the recent additions to the statutes governing employers' liabilities are already seriously affecting the earnings of the medical profession and will affect them even more when the whole body of domestic servants is brought under the protection of the Acts as they will be in July next. A few instances from the writer's own experience will act as illustration. He has for years attended the workmen in a large brewery when they have been injured at work; the employers have always paid for the attendance, but since the last Act they refuse to do so. Notice has been given to the writer that no medical attendance will be paid for now by a large landowner who for 20 years has always paid such fees for injured workpeople. An intimation has been given by the owner of a large country house that he will not in the future be responsible for medical attendance on injured servants; this gentleman has always shown the greatest liberality towards his employees when ill and a generosity not always accorded towards their medical attendants. Some years ago the writer was called in consultation on an outdoor servant of this household and operated for appendicitis on him. The master did not pay for attendance on outdoor servants, but spontaneously sent the operator a fee of 10 guineas which he had neither expected nor demanded. The other employers referred to above have been equally liberal in their treatment of sick workpeople.

These three concrete examples illustrate the spirit which the new Acts have introduced into the relations between rich and poor. And we may be sure that if liberal and generous employers assume a mental attitude so much at variance with their natural feelings of generosity a far more niggardly tone will be found general. And yet the emergencies will arise, the same frantic summons for surgical assistance will be made as is made now; the summons will be obeyed and the work will be done; in very few cases, however, will any response come to the account when sent in, and if any payment is made it will be on a very reduced scale. Neither the workman nor the domestic servant has been taught in the past to make any provision for accidents and they are certainly not going to begin to learn now. It is true that serious accidents seldom occur to domestic servants but they do occur sometimes and the necessary surgical attendance is often prolonged, owing to the relative frequency of neglected suppuration of the fingers and hands and of scalds and burns. Even if many householders avail themselves of the special policies offered by some insurance companies, which include the cost of medical attendance, such cost is strictly limited to £5, which will not be a remunerative fee for many accidents. I doubt, however, if many householders will effect these special policies; they will mostly insure at the cheapest rates.

It is hard that a profession which renders such large service to the poor without remuneration should have withdrawn from its earnings the willing contributions of the rich. This will undoubtedly be one of the effects of the new Act.

---

[2] Special Supplement, Brit. Med. Jour., July 22nd, 1905.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Overlapping Hospitals.

THERE exists in Manchester an institution called the Manchester Eye and Ear Hospital. It was established in 1888 by the late Dr. D. McKeown at the private house he occupied, 25, John-street. So far as the writer is aware no other medical man had any association with it during his lifetime and his name appears in the Medical Directory of 1906 as the one and only honorary surgeon. There was, however, it appears a committee of non-medical gentlemen. It is not too much to say, however, that but little was known of the institution by the medical profession in Manchester and it was generally looked upon as the private venture of the honorary surgeon. Of course, the similarity of name with that of the Manchester Royal Eye Hospital and that of the Manchester Ear Hospital was very likely to cause confusion both to patients and benefactors. The Royal Eye Hospital was, before the new building in Oxford-road was opened, in John-street, almost opposite Dr. McKeown's house and hospital, and even now is used for the convenience of out-patients who are a long way from the new hospital in Oxford-road. The Manchester Ear Hospital is also close by at the bottom of the street. The annual meeting of the friends of the Eye and Ear Hospital was held the other week and the report gave a sketch of the history of the hospital. Dr. McKeown died in December last and as the accumulated funds, which then amounted to £2500, "had to be applied to the purpose for which they were given, the board of management decided that the work of the hospital should be continued with such modifications as would bring it into line with the other public charities of Manchester." Last year the report states that there were 3297 out-patients and 318 in-patients. The Dean of Manchester, in seconding the report, said the hospital was passing, he understood, from private to public administration and "was approaching in its history a stage in which the support of the friends of the charities of Manchester might well be readily given to it." If there were no other institution in Manchester dealing with the eye and ear this plea would be readily granted, but as Mr. P. W. Kessler, the chairman of the Royal Eye Hospital, said, if the scheme were carried out there would be a danger of overlapping. The Royal Eye Hospital had now 106 beds and about next April would have 160, providing, he considered, ample accommodation for the district for many years to come. There were also two large out-patient departments, one almost opposite 25, John-street. He felt that the ground was already covered, and in view of the present position of so many medical charities he deprecated competition. Mr. Skemp, the secretary of the Eye and Ear Hospital, justified its existence by the public use of the institution and by its solvency. As regards the former reason, any place where the words hospital or dispensary appeared would soon be flooded with patients, either of the needy class or of that large one willing to accept anything that can be got for nothing. Mr. T. H. Davies Colley made a similar protest to that of Mr. Kessler on behalf of the Manchester Ear Hospital, a near neighbour. It was stated that negotiations were in progress that would remove any possibility of friction. The chairman of the meeting, Sir William Stephens, said the door was open for negotiations, but the board of management did not wish to have its hands tied in any way. One gentleman made a statement not pleasant for the medical profession to hear—"that the new institution was being erected for the sake of certain medical men"; that there were not enough hospitals for all the excellent medical gentlemen of Manchester. One of the medical men present wished to reply to this statement, but the chairman said there was no necessity. The greater the number of these competing and, it may be said, opposing institutions, the greater the waste of money and work, and it is to be hoped that the two objects of the institution may be so adjusted as to lessen, not to increase, the competition, sometimes unseemly, between medical charities.

Rescue by a Medical Man.

All know the deeds of bravery unostentatiously done by medical men in their daily conflict with disease, but the incident recorded below, although extra-professional, is surely worthy of mention. As Dr. H. E. Huntly of Penwortham was cycling along Broadgate, Preston, he saw a little fellow of about five years old slip on the steep embankment of the Ribble and roll down into the river where it is six feet deep. The lad had sunk twice when Dr. Huntly sprang into the river and rescued him. The boy was unconscious but the doctor brought him round by artificial respiration. But for the passing at that moment of a man possessing both pluck and knowledge the boy would certainly have been drowned.

Tuberculous Milk.

In his report to the Manchester Hospitals Sub-Committee on the working of the Manchester milk clauses, the veterinary surgeon mentions an incident of some interest. A sample of milk taken outside the city, but presumably intended for the use of Manchester families, was found to contain tubercle bacilli. When he went to the farm from which it had come, the farmer at first refused to allow him to examine the cows, saying that he had an agreement with the milk dealer that none of his milk should be sold in Manchester and the dealer admitted this understanding. One of the cows had marked tuberculosis of the udder, probably of some months' duration. The local authorities are giving the case their attention. The incident shows that the farmers, at any rate some of them, do not like the Manchester scrutiny of the milk, but the compact with the dealer and its occasional violation also show "the necessity for increased stringency in the protection of our milk-supplies."

Rain in the Milk.

At Blackburn last week a farmer summoned for selling milk in which, according to an analyst's certificate, there was from 8 to 10½ per cent. of added water, offered a somewhat unusual defence. It was that the milk contained 3·26 per cent. of butter fat, which was 0·26 per cent. above the recognised standard; that immediately after milking it was brought out of the shippon and placed on an uncovered stock in the yard; and that on the morning in question it rained heavily and was on the stock an hour and a half. Since then the stock had been covered over, so it was now protected from the rain. It is not often that the heavens are called upon, at least so one thinks, to assist in the adulteration of milk. The magistrates seem, however, to have been half convinced, for they dismissed the case, though with costs.

Overcrowded Workhouse.

At a meeting of the Prestwich guardians held on May 15th the crowded state of the workhouse was considered, especially with regard to the condition of the imbecile and sane epileptics. There are now, it appears, 26 women and 16 men in the imbecile wards who are sane epileptics. This of course cannot be justified and it was eventually arranged by the board that a large number of the sane epileptics should be sent to the Langho colony.

May 21st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Meeting of the British Dental Association at Cardiff.

THE annual meeting of the British Dental Association was held at Cardiff on May 18th, 20th, and 21st. The President, Mr. J. C. Oliver, in his opening address, urged the importance of making a systematic examination of the teeth of school children. He stated that as a result of extensive observation it had been ascertained that among the school children of this country only about 3 per cent. had sound teeth, and he contrasted this condition with that found in connexion with a recent discovery near Cardiff of ancient British human remains where out of 30 skulls examined only three had teeth which displayed any signs of decay. The same subject was dealt with by Mr. W. Cass Grayston of Scarborough. He considered that a scheme for the examination of the teeth of school children which was compulsory would be more likely to succeed than one which was voluntary. But if compulsory it must be free. He was of opinion that one dentist devoting his whole time to the work could not look after more than 1500 children in one year and on the basis of an annual salary of £300 to a dentist this would mean a yearly expenditure for England and Wales of about £400,000 for the treatment of only one-third of the school children in the country. He suggested that if the State would not pay so large a sum it could be provided by a contribution from every school child of 1*d*. weekly. Mr. G. Cunningham said that in Cambridge the corporation had appointed a dental officer at a salary of £50 per annum to examine the teeth of all the children attending the public elementary schools. The duties of this gentleman did not include any treatment but financial assistance had been offered privately for the provision of attention in this direction. This question of the care of children's teeth is very appropriately discussed at Cardiff, for about five years ago Mr. J. Percy Oliver addressed a letter from the South Wales branch of the Dental Association to the Cardiff board of guardians, urging the necessity for a systematic examination of the teeth of the children under the care of the board. The reading of the letter was met by bursts of ironical laughter and after one member had remarked that the letter was of no importance it was decided to let it lie on the table. As a commentary upon this action of the board of guardians it is pleasing to be able to record the remarks of the Lord Mayor of Cardiff when he welcomed the Dental Association to the city last week. He spoke of the care of the teeth of school children as a matter of paramount importance and hoped that the time would soon come when the children attending the public elementary schools would be periodically examined and their teeth attended to by skilled dentists. Sooner or later, he said, the Government would have to take the matter up as one of national importance.

The Residences of Poor-Law Medical Officers.

The Cardiff board of guardians, at some of its meetings, has been discussing the residential qualifications of one of its district medical officers. The gentleman in question occupies a villa outside his district but also has a surgery which is within his district. At the meeting of the guardians held on May 11th, a letter from him was read repeating his former statement that he resided in his district. Several guardians took exception to this and, after some discussion, a subcommittee was appointed to consider the matter, the chairman pointing out that the question at issue was one of law as well as of fact, and that a man might have two houses.

Didworthy Sanatorium for Consumptives.

The fourth annual meeting of the subscribers to the Didworthy Sanatorium, Dartmoor, was held on May 15th. The medical report stated that 94 patients were treated during 1906 as compared with 66 in 1905. Since the opening of the sanatorium in 1903 there have been 247 patients admitted, and the results obtained by treatment have been very satisfactory. The committee in the report alludes in sympathetic terms to the death of the late medical superintendent (Mr. J. C. Fleming). The new wing of the building providing accommodation for 35 patients was opened last May and the total cost of the erection of the sanatorium up to the present has been £9532, or £240 per bed, which compares favourably with similar institutions. The financial statement was satisfactory and showed that Sir Massey Lopes has given another £500 for the endowment of the institution. The Earl of Mount Edgcumbe was elected President and Dr. R. Hogarth Clay was appointed chairman of the management committee.

Bristol Lunatic Asylum.

The annual report of the visiting committee of the Bristol Lunatic Asylum for 1906, which has just been issued, states that at the close of that year the institution contained 923 patients (422 males and 501 females). The Commissioners in Lunacy have approved of plans giving accommodation for 90 additional beds. The work will be commenced shortly as the male wards are overcrowded. The committee in concluding its report expresses its appreciation of the manner in which the medical superintendent (Dr. J. V. Blachford) and his staff have performed their duties during the past year.

May 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Volunteer Medical Officers.

THE Scottish Volunteer Medical Officers' Association held its annual dinner last week at St. Enoch Station Hotel, Glasgow. Colonel G. T. Beatson, C.B., V.D., presided, and amongst those present was Colonel T. M. Corker, R.A.M.C., principal medical officer of the Scottish Command. In his speech Colonel Beatson, after dealing with Mr. Haldane's army scheme in so far as it affected the Volunteer Force, went on to speak more especially of the Volunteer Medical Service. In his opinion the existing Volunteer Medical Service was not satisfactory and their association should devote its energy and influence to have it remedied. They should go forward in one united corps—the Royal Army Medical Corps (Volunteers). To it every medical officer should belong and should be attached to it on joining. Once qualified he should take up corps work or regimental work as he liked. Under every regimental surgeon there should be a fixed and recognised body of men for sanitary and ambulance duties alone. These men should be supernumerary to the regiment and capitation grant should be drawn separately for them. Further, every regiment should have its own ambulance equipment under its own medical officer. This medical officer might wear the uniform of his regiment if he liked, but he must have the corps uniform, and for it only should he get an allowance. It was in such matters that the usefulness of an association made itself felt. In replying to the toast of "Our Guests" at a later period of the evening Colonel Corker said that he did not think the Volunteers would really be swept away. He was prevented from saying much that he knew of Mr. Haldane's scheme, but he pledged himself to do all he could to improve the medical service of the army.

The Decrease of Cerebro-spinal Meningitis.

Dr. A. K. Chalmers, medical officer of health of Glasgow, reports that during the fortnight just ended there were 45 deaths from cerebro-spinal meningitis in Glasgow, a decrease of 14 as compared with the previous fortnight. In Edinburgh no fresh case has been reported this week, but there were 43 notifications and 36 deaths during April. A soldier from Perth Barracks, who was removed last week to the fever hospital at Friarton, died in that institution shortly after admission. Although sporadic cases are still occurring here and there in the country districts it really seems as if the epidemic were on the decrease.

Completion of Galashiels Consumptive Sanatorium.

The small-pox hospital at Galashiels, which has been fitted up as a sanatorium for the treatment of consumptive patients by private subscription, is now ready for occupation, and it is expected that five patients will be admitted this week. The situation and internal arrangements of the buildings are all that could be desired.

Electric Cooking and the Purity of the Air.

The electricity committee of the Glasgow corporation has decided to take two houses in the High-street corporation property for six months, at a rent of £9 each, for the purpose of conducting experiments regarding the effect on the atmosphere of the more general use in dwelling houses of gas-stoves for cooking purposes.

Public Health of Ross and Cromarty: Annual Report.

Dr. W. Bruce, medical officer of health of the county of Ross and Cromarty, has issued his annual report. The health of the county during 1906, judging by the death-rate, was better than it has been for the past two years. In 1904 the death-rate was 15·739 per 1000, in 1905 it was 16·297, while in 1906 it was 14·967. The insulo-rural rate for Scotland during the past year was 15·1. There is still some overcrowding on the mainland and some of the crofters' houses in the western and south-western districts are in a bad state, but otherwise there are no conditions dangerous to health on the mainland. In Lewis there are still much overcrowding and many black huts, while the water-supply, as a rule, is open to contamination and there is a deficiency in the means of coping with epidemic diseases. The tide of emigration, which seems to be setting in, will, to a certain extent, relieve the overcrowding. There is still much lack of knowledge among the general population as to the laws of health. While the schools on the east coast, with one or two exceptions, are in good sanitary order, it is otherwise on the west coast and in Lewis. The most clamant defects are the want of plenty of pure water and the filthy condition of the cloak-rooms and usual conveniences. A system of inspection of workshops is being inaugurated. By the munificent kindness of Colonel and Mrs. Stewart Mackenzie of Seaforth a sanatorium for pulmonary tuberculosis has been presented to Ross and Cromarty. This will consist in the first place of 12 beds and as the demands for admission grow larger that number will step by step increase. Dairies on the whole were found to be satisfactory. The population for the county this year is estimated at 63,138, showing the usual steady decline all over the county with the exception of the Lewis district where there is a small increase of 24. The birth-rate is almost constant. The deaths from infectious diseases of all kinds amount to 158, of which about five-sixths are contributed by tuberculous disease.

May 21st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Cerebro-spinal Fever in Belfast.

AT the weekly meeting of the public health committee held on May 16th it was reported that for the week ending May 11th 29 cases of "spotted" fever had been reported, that is, one less than in the previous week. Since the last meeting of the committee 22 cases of the disease had been notified, bringing the total number up to 420, while the total deaths were 295. As to the question of not permitting the friends of the patients to visit them in hospital, Dr. A. G. Robb, physician to Purdysburn Fever Hospital, wisely stated that to do so would only create a panic. He believed that nearly 1500 persons had visited the hospital to see patients and to remove the bodies of their dead friends. None of these visitors had contracted any disease from visiting the hospital. He considered that visitors to the hospital to see these cases under the existing regulations ran no risk of infection, but overalls were being provided for such visitors which it was hoped would allay the dread which they sometimes felt. With reference to the vaccine mentioned by Dr. M. H. Gordon the English Local Government Board wrote that the investigations of Dr. Gordon and Dr. T. J. Horder had not been completed and on these grounds the Board was not able to accede to the application of the committee.

Medical Benevolent Society of Ireland.

At the annual meeting of the Belfast branch of the above society held in the Medical Institute on May 17th (Professor J. A. Lindsay, the President, being in the chair) it was reported that the amount received from all sources had been for the past year £157 12*s.* 6*d.* Of the 200 medical men practising in Belfast 70 gave nothing, while from nearly 200 in the country districts only 46 responded. Dr. G. L. Fielden was appointed treasurer and secretary in place of Dr. R. Purdon, resigned.

Royal University of Ireland: Suggested New Regulations in Medicine.

The medical committee of the Royal University of Ireland having recently suggested certain changes in the medical curriculum, a meeting of the professors and lecturers at Queen's College, Belfast, as well as of the medical and surgical staff of the Royal Victoria Hospital was called together at Queen's College on May 16th to consider the matter. The feeling of the meeting was that it was unwise at present, in prospect of changes in Irish University education and also because the question is likely shortly to be discussed at the General Medical Council, to make any alterations; especially to enact that a minimum of six years should be compulsory for the medical course. Everyone feels that one of two things must soon happen: either a boy at school must study several subjects—chemistry, physics, zoology, and botany—and be examined on these when he enters college, so as to begin at once anatomy and physiology, or a six years' course—as occurs in the continental schools—will be absolutely necessary in medicine; but it is thought that the present time is inopportune to make such an experiment in Ireland. When the five years' course was arranged the idea was to give more time for the purely professional subjects which are to form the life-work of the average medical man, but unfortunately the preliminary subjects were enlarged and extended and the five years' course has really been of little help for the three final professional subjects—medicine, surgery, and midwifery. So far as medical students are concerned the non-professional scientific subjects are being less and less taught in their technical or practical bearing on medicine and surgery and more as pure sciences, and so the work of the average student is being over-burdened and less time is given for acquiring a practical knowledge of those subjects which will enable him to make his living. Many points in this new scheme are excellent and will probably be adopted in the future, but it would be wiser, it is thought by many, for nothing to be done until all the medical schools directly affiliated with the Royal University of Ireland have had time to discuss the proposed changes and to send their criticisms to the medical committee of the university.

The Belfast Health Commission.

The Belfast Health Commission adjourned on May 18th, the principal evidence during the week being that of Dr. H. O'Neill in reference to the public health committee and that of Dr. J. McCaw on infantile mortality. Neither witness was complimentary to the municipal efforts. Owing to the fixed engagements of some of the commissioners there will soon have to be a suspension of the sittings until July, so that it is hoped that at their next sitting they will finish the taking of evidence. The chairman truly said, "People might talk of the length of the inquiry, but if the report of the commission was to be of real value to Belfast it must be very full and complete."

Post-Graduate Classes at the Royal Victoria Hospital, Belfast.

A post-graduate course on similar lines to that which proved so successful last year will be held this year at the Royal Victoria Hospital from July 1st to July 14th. Mr. Andrew Fullerton, 30, University-road, Belfast, is the honorary secretary and from him any further information as to the details of the course can be obtained.

County Antrim Infirmary, Lisburn.

From the twenty-first annual report of the above institution it appears that during the past 12 months there were 376 intern and 454 extern patients. A sterilising chamber has been built for the operation room and a complete x ray installation has been presented to the infirmary, to be at the service of the medical men of Lisburn and the neighbourhood. The daily average of patients in the infirmary was 36·1 as compared with 33·7 during the previous year. The financial statement showed that the annual expenditure on each patient was £4 13*s.* for drugs and dressings and £10 17*s.* for food.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Saliva of Syphilitic Patients.

M. Follet read a paper on this subject at the April meeting of the Biological Society. He had been impressed by the number of cases of contamination by the saliva of syphilitics of articles such as drinking glasses, glass blowers' pipes, gummed paper moistened with saliva and stuck on a wound, and mouth-pieces of musical instruments, and he had applied new staining methods, which he described, to identify the treponema pallidum (spirochæta pallida) in a large number of syphilitics. By this means from untreated cases with chancres several months old he had been able to count in some fields of the microscope the enormous number of from 200 to 300 spirilla; it is true that all the spiral forms did not represent treponema pallidum, but the number of spirilla which can be found in the saliva of certain syphilitics, even when they do not present mucous plaques, is very striking. As a control M. Follet examined the saliva of a number of healthy persons, and the few spiral forms that he occasionally found could not be confused with the treponema.

Chronic Appendicitis and Muco-membranous Entero-colitis.

At the Academy of Medicine on May 7th M. Richelot read a paper in which he maintained that intractable intestinal complaints, including muco-membranous entero-colitis, are often cured by the removal of an appendix which is slightly but chronically inflamed. In support of this theory he described ten cases in which appendicitis of a comparatively mild type was succeeded by muco-membranous enteritis and other abdominal troubles and in which all these complications cleared up after appendicectomy. M. Richelot also mentioned several other cases of patients who had for months and even years complained of intestinal troubles that could not be attributed to any definite cause, which he had seen cured by operation performed on very faint indications or as a last resort; he considered that these were undoubtedly due to a form of appendicitis that could not be recognised clinically.

A Case of Mixed Leprosy: Atoxyl in Large Doses.

M. Hallopeau and M. Bondet, at the French Society of Dermatology and Syphilology, described a case of leprosy which had seemed hopeless. The patient had suffered for a long time and presented very extensive anæsthesiæ, multiple nodules, and perforating sores; for some weeks ulcerative tuberculous lesions had been present on the side of the arch and velum of the palate, which threatened to destroy the uvula. Prolonged treatment by chaulmoogra oil had no effect. Considering the great analogy which is presented between syphilis and leprosy in their evolution and symptoms it seemed indicated to try on this patient the treatment by large doses of atoxyl, with which M. Salmon obtained such remarkable results—results which M. Hallopeau and M. Bondet have frequently been able to confirm.

Gunshot Wound of the Abdomen.

At a meeting of the Surgical Society held on May 15th M. Rochard read for M. Malartic of Toulon an account of the following case. A man had received a shot from a revolver in the abdomen. Signs of internal hæmorrhage were present and an immediate laparotomy was performed. Two perforations were found in the stomach and four in the intestines. These were sutured and in addition a wounded branch of the mesenteric artery was tied. The patient had also a fracture of the ninth rib, and following on this he developed pneumothorax and an empyema. On the fifteenth day M. Malartic opened this and despite his multiple injuries the patient recovered completely.

Menstrual Irregularities and Irido-kératitis.

The ocular troubles which sometimes accompany menstrual irregularities in women aged from 20 to 25 years have not as yet received sufficient attention. At the recent congress of the French Ophthalmological Society held on May 7th, M. Bouchard of Limoges said that in four cases of irido-keratitis in women with irregular menstruation he had observed that all the usual treatment was useless, but cleared up entirely when the menstrual functions became normal. The participation of the eye in numerous general disturbances of health is said to be due to the elimination of toxins by the fluids of the ocular globe.

(FROM OUR OWN CORRESPONDENT.)

The Prussian Army Medical Corps.

IN a recent number of the *Deutsche Medizinische Wochenschrift* Surgeon-General Werner gives an account of the progress which has been made in the organisation and the training of the Prussian Army Medical Corps. He states that there are at present 1716 army medical officers on the active list, as compared with 1261 in the year 1877, and that this increase is relatively much greater than the increase of the army in general. These figures do not include either (1) the Bavarian, Saxon, and Würtemberg portions of the German army, which have their own army medical corps, reproducing in every detail exactly the same organisation as the Prussian portion; or (2) the medical officers serving in the colonies with the colonial forces; or (3) the young medical men who pass their legal time of military service in the medical corps. The Army Medical Corps consists of the following officers:—One Generalstabsarzt (staff-surgeon-general and chief of the Army Medical Corps, having the rank of lieutenant-general); four Sanitäts-inspecteure (inspectors, having the rank of major-general, whose duty it is to inspect the medical service of several army corps and who in war time are the heads of the medical service of an army); 19 Generalaerzte (surgeons-general, having the rank of colonel and being the heads of the medical staff of an army corps); 38 Generaloberaerzte (divisional surgeons, having the rank of lieutenant-colonel and being the heads of the medical service of the divisions); 359 Oberstabsaerzte (surgeons, having the rank of major, most of whom are the chiefs of the medical service of regiments or hold similar appointments); 447 Stabsaerzte (staff-surgeons, having the rank of captain and acting as chief medical officers to battalions of infantry, &c.); and 347 Oberaerzte and 501 Assistenzaerzte (surgeons, having the rank respectively of senior lieutenant and lieutenant and holding various appointments chiefly as assistants to the medical officers of higher rank). The grades of inspector and divisional surgeon are comparatively new creations, dating back only a few years; recently also the army medical officers have to some extent been raised in relative rank. The strength of the corps prescribed by the Budget is much greater than the actual force, the vacancies being filled partly by medical men who pass their period of medical service in the army medical corps. A great improvement has been introduced by the establishing of post-graduate courses of four weeks' duration, which originally were held in Berlin but now are held in other university towns as well, so that every army medical officer on the active list is required to attend such a course every fourth year. Special courses have been arranged for the medical officers of the reserve. In addition to these courses and lectures army medical officers of special ability may hold appointments in civil institutions for two or three years, such civilian appointments being reserved to them whilst they continue to belong to the army. These appointments include assistantships at university clinics, important municipal and private hospitals, lunatic asylums, and hygienic and other institutions. The number of these appointments during last year was not less than 110. Since the year 1902 courts of honour have been constituted after the pattern of those existing for the other officers of the army.

Tuberculosis of the Vulva.

At a recent meeting of the Berlin Surgical Society Dr. Wolff described the case of a woman of 51 years of age, who had for the last six months suffered from an ulceration of the left labium. As the clinical symptoms were incompatible with cancer and syphilis the diagnosis of a tuberculous ulcer was made and this opinion was confirmed when the diseased tissues were examined microscopically after removal. The patient had previously suffered from tuberculous inflammation of tendinous sheaths and on a bacteriological examination of the sputum being made the presence of pulmonary tuberculosis was ascertained. Dr. Wolff considered that the ulcer of the vulva was produced by an embolus. Cases of this kind were very rare and it was remarkable that vulvar tuberculosis had a decided tendency to be confined to the vulva without ascending to the uterus, tubes, and ovaries.

Enlargement of the Hypophysis Cerebri.

In the Verein für Innere Medicin Dr. Schuster recently showed a case of Enlargement of the Hypophysis. The patient, who was a man, 33 years of age, had complained of headache and amblyopia, which finally led to almost complete amaurosis. Quite lately he observed that his hands had increased in size so that his gloves no longer fitted and that his nose had become larger. On examination the patient's skin was found to be very pale and dry, and its condition resembled that seen in myxœdema. The nose, the hands, and the fingers were slightly enlarged, but the jaw and the tongue were of normal size. The left eye diverged outwards and its reaction to light as well as the power of accommodation were almost lost. Both optic nerves were atrophied. The right angle of the mouth was less moveable than the left one; a slight tremor of the tongue was present. The mobility and sensibility of the skin and the reflexes were normal; the testicles were atrophied and sexual power was lost altogether.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

The Physiological Action of Digitalis and Strophanthus.

Dr. Carl Tigerstedt at Helsingfors has carried out some interesting investigations into the effect of digitalis and strophanthus on the circulation. Though experimenters such as Bradford, Phillips, and Brunton have done much to elucidate the question it is as yet undecided whether the increase in the blood pressure produced by injection of digitalin, &c., into the circulating blood is due to an augmentation of the heart beat or to a contraction of the peripheral vessels or perhaps to both of these factors. Dr. Tigerstedt has now made an attempt to attain a definite result by means of the introduction into the ascending aorta of a "stromuhr" to estimate the volume of blood expelled by the heart in the course of a second. The determining of this volume, of the blood pressure, and of the frequency of the pulse before and after injection of the substances in question has led him to state that the increase in arterial tension caused by digitalis and strophanthus is chiefly due to a contraction of the peripheral vessels. The part played by the augmented output per second of the heart is considerably less important and is generally to be found only during the period immediately subsequent to the injection before the pressure has reached its maximum.

A Case of Impaction of a Foreign Body in the Bronchus.

At a recent meeting of the Gothenburg Medical Society Dr. Kruse reported a case of a foreign body in the right bronchus of a boy, seven years of age. Shortly after the aspiration a little ecchymosis was detected by the laryngoscope on the anterior wall of the trachea from 1 to 1·5 centimetres below the glottis. Examination by means of the x rays showed the foreign body, a metallic pencil case, on the right side of the sternum, with its upper end level with the sternal insertion of the fifth to sixth rib. The interest of the case lies in the fact that the *vis medicatrix naturæ* alone brought the case to a successful issue, as the patient on the next day was seized with a severe coughing fit, during which the foreign body, which measured 2·5 by 1 by 0·4 centimetres, was expelled.

The Bactericidal Properties of Tears.

Dr. C. Lindahl has examined the bactericidal powers of tears and found them very pronounced to staphylococci and streptococci, but not, as a rule, to pneumococci. The bactericidal effect is not due to the inorganic components of the fluid, but partly to the leucocytes and, it would seem, partly also to certain substances of enzyme nature present in tears. Thus, lacrymal fluid that has been heated to a certain temperature and afterwards cooled again to the normal fails to prevent the growth of bacteria to the same degree as when it has not undergone any previous heating.

Professor Berg on Gastric Carcinoma.

At the inauguration of the new quarters of the Swedish Association of Physicians in Stockholm Professor John Berg delivered an address on his experience of operation for malignant tumour of the stomach during the years 1887–1906. The total number of such operations performed by him (in a few cases by his assistants) was 225. Of these 79 were resections of the stomach, 62 of which were made during the last ten years with only nine deaths, presenting a mortality of 14·5 per cent. As to the possibility of eradicating a malignant tumour of the stomach Professor Berg said he had one case well ten years and another five and a half years after the resection. But even if in most of the cases only a temporary palliative effect was procured he preferred to resect instead of performing a gastro-enterostomy even in cases where a radical operation did not seem possible, as the remainder of the patient's life was so much more comfortable when a resection had been performed.

Street Collection by Ladies for Charity in Copenhagen.

On May 7th the "Children's Relief Day" was celebrated for the fourth time in Copenhagen. The idea of this festival originated with a prominent member of the profession, Dr. Carlsen, and he had the good luck to interest other people in his idea to such a degree that the "day" seems now to have become a permanent institution. What Dr. Carlsen wished was to raise every year a considerable sum of money for the benefit of the infants' asylums, certain children's hospitals, &c. During the last four years he has succeeded in collecting on that one day in Copenhagen about £6000 each year. The way in which the money is extracted from the public is rather original and has largely contributed to make the day a popular success. About 10,000 boxes (of the shape of a savings' box) are distributed to trustworthy persons, mostly young ladies of the middle classes, who patrol practically all streets of the town, especially the great thoroughfares. As soon as a passer-by is espied by one of the fair collectors she hurries towards him jingling the box and asks prettily for a mite, a request which it is very difficult not to grant. The crowds of people enjoying this peaceable pillage, the inharmonious "music" of all descriptions produced on every side, with the incessant and deafening jingling of the boxes, create an impression of popular hilarity perhaps unprecedented under a northern sky. The scheme has been imitated in other towns of Denmark, Sweden, and Germany, but to my knowledge not yet in England.[1]

May 20th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Ulisse Aldrovandi.

WHIT-WEEK finds the "Mother of Universities" putting the finishing touches to its programme for the celebration of the third centenary of the death of Ulisse Aldrovandi, one of the greatest among the many great nature-students produced by Italy. A native of Bologna, where he was born in 1522, Aldrovandi had thoroughly mastered the Hippocratic principle that medicine, or the healing art, is a branch, if not, indeed, the culmination, of nature-study, and immediately after taking the "summi in medicina honores" he devoted himself, mind and soul, to the inductive sciences on which medicine is based, or rather out of which it springs. Physics, the so-called "natural philosophy," engrossed much of his attention, and from that, with its foundation in mathematics, he proceeded to the natural sciences proper, mineralogy, botany, and zoology. Called to the botanical chair in the Bologna School and appointed superintendent of the botanic garden in connexion with it he gave a powerful impulse to the study and prepared successive relays of nature-students for what was afterwards to be the profession of their choice—that of medicine. Enthusiast as he was in exploring the vegetable world he never lost touch with the sister realms of mineralogy and zoology, and visited the most distant countries in the quest for "specimens" to be afterwards classified and put in evidence for the Bologna School and for the outside world whom he attracted to it. In this strenuous life he exhausted his material resources as well as his bodily powers and at length succumbed, poor, blind, and ill, in the Bolognese hospital where he was allowed to die. He left behind him quite a library of publications, including six folio volumes on entomology and ornithology, in the preparation of which he employed a numerous and able staff of draughtsmen and wood engravers. This work was continued on the same lines after his death—"being dead he yet spoke" to the scientific world of his time. It is to commemorate his life and work that Italy, led by Bologna, is now about to celebrate his third centenary and already an organising committee of Italian nature-students and medical men is coöperating with sympathisers from other countries and seats of learning for the worthy carrying out of the programme. King Victor Emanuel III. is the honorary president of the committee, while the citation of a few names of the foreign members will suffice to indicate the importance attached to the celebration in both hemispheres. Thus we have Agassiz of New Cambridge and Bayly Balfour of Edinburgh; Fries of Upsala and Haeckel of Jena; Liversidge of Sydney (New South Wales) and Loeve of Tokio; Pereira of Lisbon and Sanse of Leyden; Spegazzini of Buenos Ayres and Stephanesco of Bucharest; Villada of Mexico and Wiesner of Vienna—to cull a few from a lengthy and distinguished list. Among English universities, Oxford, I see, has already nominated its delegate, and I have no doubt other seats of learning and scientific associations in the British Isles will be worthily represented on June 12th, the day on which the "Mother of Universities" pays her tribute (long over-due) to her eminent son.

An "Italian Association for the Advancement of Science."

In keeping with the now universally recognised principle that nature-study and medicine are parts of an organic whole, the latter "crowning the edifice" which the former has prepared, a movement, medical in its inspiration and inception, is now wellnigh carried to completion for the institution on British lines of an "Italian Association for the Advancement of Science." Proposed at Milan last year it has now taken form and development under capable organisers, including Professor Romiti of Pisa, whose distinction as an anatomist was worthily acknowledged last year at the Aberdeen quatercentenary by the bestowal of an honorary degree. The first meeting will be held at Parma in September next, when it is hoped that the sister Powers of Europe, as well as those of the New World, will assist in an auspicious "send-off." Invitations will be issued to the nature-students and men of science of other countries to take part and the season, the early autumn, ought to present no obstacle to their coming. Italy has many associations for the advancement of special sciences—none more flourishing than the medical—but, as Professor Romiti has ably put it, she has yet to form an association which shall "represent the synthesis" of these. Attempts were made in 1839 and 1875 to start such an association on the British model, but though they proved attractive and—the latter especially—fruitful in valuable work they have had no successor. Now, however, the attempt has been renewed and from the organisation behind it it is fair to conclude that the association will not only justify its programme but will have "come to stay."

---

[1] The collection of money for charitable purposes by ladies in the public streets is not unknown in England, though we do not think it has yet served to constitute a popular festival or has been attended with such results as our correspondent quotes.—ED. L.

May 20th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

PLAGUE continues in Sydney and Brisbane. Six cases have occurred in Sydney since my last communication, two of which were fatal, and many plague-infected rats have been found. In Brisbane two cases were reported and removed to the plague hospital in one day and rats were found infected in great numbers. The total number of cases of plague in New South Wales since the disease first occurred in 1900 is 566, with 192 deaths. The largest number occurred in 1900, 303 being reported in Sydney, with 103 deaths. In 1901, only two cases and one death; in 1902, 138 cases and 38 deaths; 1903, two cases and no deaths; 1904, ten cases and six deaths; 1905, 18 cases and five deaths; 1906, 20 cases and eight deaths; and this year so far 29 cases have been reported and eight deaths. At Newcastle 15 cases occurred with four deaths, and four cases, all fatal, at Kempsey. In each year the greatest number of cases has been in March and April. Destruction of rats is vigorously carried out in Melbourne and the berthing regulations are strictly enforced, and so far no cases of plague have occurred.

Cerebro-spinal Meningitis.

Cerebro-spinal meningitis exists in a sporadic form in Melbourne. During the past 12 months four cases have been treated at the Children's Hospital and one at the Melbourne Hospital. The disease has never shown any tendency to become epidemic.

Epidemic Disease in Victoria.

The following return of certain diseases for the fortnight ending March 9th, with a comparison of the average returns for the same period in the years 1903 to 1906, was presented at a recent meeting of the Board of Public Health of Victoria:—

—	In the whole State.		In the metropolitan area.	
	1907.	Average. 1903–1906.	1907.	Average. 1903–1906.
Typhoid fever cases ...	100	189	27	62
Typhoid fever deaths ...	2	10	0	5
Diphtheria cases	34	56	20	22
Diphtheria deaths ..	0	2	0	1
Scarlet fever cases ...	8	71	2	42
Scarlet fever deaths ...	0	0	0	0

Australasian Medical Congress.

The next Australasian Medical Congress is to meet in Melbourne in October, 1908, under the Presidency of Professor H. B. Allen. A representative organisation committee has been appointed, with Dr. Henry C. Maudsley as secretary-general and Mr. G. A. Syme as treasurer. The arrangements of the sections have been completed and a circular has been drafted. It was feared that some difficulty might be caused by the refusal of the Government to print the transactions, as the Government of each State in which the Congress has been held has hitherto done, but a deputation waited on the Premier and after discussion the Cabinet agreed that the necessary printing should be done at the Government printing-office.

Study of Tropical Diseases.

THE Bishop of North Queensland has submitted a memorandum to the committee of the Townsville Hospital suggesting that Townsville should be made the seat of an Institute for the Study of Australian Tropical Diseases, under the direction of the Medical Faculty of the University of Sydney and in constant correspondence with, and relation to, the pathological and other scientific departments of the Universities of Melbourne and Adelaide. He suggests that such an institute should be subsidised by the Commonwealth and Queensland Governments. The scheme has been approved formally by the Council of the University of Melbourne.

Medical Curriculum, Melbourne.

At the last meeting of the Senate of the University of Melbourne the medical curriculum was further amended. Clinical medicine and clinical surgery are to be separate subjects of examination with a separate board of examiners. The final examinations are to be held a fortnight earlier. The new curriculum is on its trial and the transition from the old to the new has been got over without great difficulty. Students, however, complain that the third year's arrangements are not satisfactory. A new difficulty has arisen in a grave shortage in the supply of subjects for dissection. There are no workhouses or poorhouses in Victoria and the present supply comes from unclaimed bodies from the various hospitals and an institution formerly known as the immigrants' home, which is practically a poorhouse, now called the Victorian Homes for the Aged and Infirm. Another institution of a similar character, really a poorhouse, is the Benevolent Asylum. Dr. R. J. A. Berry, the new professor of anatomy, recently wrote to the committee of this charity asking for assistance in providing subjects but the committee declined.

Infant Life Protection.

The need for more efficient means of protecting boarded-out infants is constantly emphasised at inquests held on these unfortunate children. The Chief Secretary of Victoria is considering proposals on the subject, one of which is the employment of female inspectors in place of the police, and another that the children should be inspected up to five years instead of two as at present. In Sydney an attempt to improve the health of infants has been made at the out-patient department of the Women's Hospital. The mothers who have been confined in the hospital are invited to bring their infants to the hospital for inspection, honorary medical officers attending on one afternoon a week for the purpose. The infant is weighed and the record handed to the medical man. If unsatisfactory the child is examined and the cause ascertained and remedied if possible. The work is intended to be educational, to help mothers to keep their babies in good health. This "infants' observation" work has only been in operation for five months but the results have been satisfactory. Other poor women besides those who have been patients are invited to bring their infants for "observation."

Health Administration in Victoria.

Dr. Norris, chairman of the Board of Health, Victoria, has prepared an exhaustive memorandum on the reform of local health administration by the constitution of combined sanitary districts with whole time and expert officers of health. These officers would report simultaneously to the local board and the Board of Health and if the latter's coercive powers were somewhat increased it would be in a position to move the local councils which failed to use the powers that they possess. The administration of the Health Act by the Board inspection of the local bodies does not meet with Dr. Norris's approval.

Chinese Herbalist's Treatment.

At an inquest recently held on a man at Myrtleford, Victoria, the evidence showed that the deceased had suffered from lung disease for three years and for eight months had been treated by a Chinese herbalist who ordered the withdrawal of milk, cream, fats, and water, and the drinking of large quantities of infusions of herbs, which made him sick. The Chinaman had been paid £75 and had promised to effect a cure. The jury brought in a verdict that the deceased died from tuberculosis and that death was unduly accelerated by unskilful treatment.

Presentation to a Medical Man.

Mr. E. Ken Herring, on leaving Shepparton to practise in Sydney, was presented with a smoker's outfit by the Shepparton Bowling Club. Mr. and Mrs. Herring were presented with a collection of silver ware and Mrs. Herring also received a silver afternoon tea service from the Shepparton ladies.

Medical Man attacked by Lunatic.

Dr. Montgomery, medical superintendent of Claremont Hospital for the Insane, West Australia, has been violently attacked by one of the inmates, who struck him on the head with a stone, rendering him unconscious. He is recovering satisfactorily.

April 16th.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board, under the provisions of Rule 4 of the Rules of Procedure, was held at Caxton House, Westminster, on May 16th, Dr. F. H. Champneys being in the chair. The Board considered charges as stated after their names against the following midwives whose names were ordered to be erased from the roll: Ann Bamford, that being in attendance at a confinement, the patient suffering from puerperal fever, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Eliza Bill, that being in attendance at a confinement she was intoxicated and incapable of performing her duties. Caroline Cartledge, that being in attendance at a confinement, the patient suffering from foul-smelling discharges, from headaches, and from abdominal pains, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Harriet Cooper, that being in attendance at a confinement, being unable to deliver the child, the labour being abnormal, she refused to have a registered medical practitioner sent for. Caroline Emma Fisher, that she did not use or possess the appliances or antiseptics required by Rule E 2, that she did not keep a register of cases, and that she was not scrupulously clean and did not wear a dress of washable material. This midwife signed a paper requesting the Board to remove her name from the roll. Elizabeth Ann Goodall, that being in attendance at a confinement she did not wash the patient at any time nor did she give full directions for securing the comfort and proper dieting of the mother and child during the lying-in period and that she sent an uncertified person to act as her substitute. Seline Hitchins, that being in attendance at a confinement the perineum being seriously ruptured, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Sarah Ann Homer, that being in attendance at a confinement, the patient suffering from severe abdominal pain with swelling and signs of insufficient contraction of the uterus, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Sarah Skitt, that being in attendance at a confinement, the patient being ill with a temperature above 100·4° F. and a foul-smelling discharge, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Thurza Smith, that being in attendance at a confinement, the placenta not having been expelled an hour after the birth of the child, she did not decline to attend alone and advise that a registered medical practitioner be sent for. The following midwives were censured by the Board after the following charges stated after their names had been considered: Mary Brookes, that being in attendance at a confinement, the child's eyes being inflamed at birth, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Eliza Burgess, that being in attendance at a confinement, the patient being a primipara, and there being a breech presentation, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Elizabeth A. Long, that being in attendance at a confinement, the child suffering from septic infection of the cord, she did not decline to attend alone and advise that a medical practitioner be sent for. Caroline Lovatt, that being in attendance at a confinement, the patient being delirious, she did not decline to attend alone and advise that a registered medical practitioner be sent for. Mary Morrall, that being in attendance at a confinement, the patient suffering from puerperal fever, she did not decline to attend alone and advise that a registered medical practitioner be sent for.

Obituary.

ROBERT BARNES, M.D. LOND., F.R.C.P. LOND., F.R C.S. ENG. (HON. CAUSÂ.),

CONSULTING OBSTETRIC PHYSICIAN TO ST. GEORGE'S HOSPITAL.

Robert Barnes was born in Norwich on Sept. 4th, 1817. His father, Philip Barnes, was an architect, a member of an old Norwich family, who having private means did not practise his profession. Philip Barnes migrated to London and was the founder of the Royal Botanic Gardens in Regent's Park. Robert Barnes's mother's maiden name was Miss Harriet Futter. His grandfather was a Norfolk squire of good property. When he was about nine years old young Robert Barnes was sent with his elder brother to school at Bruges. His father was one of the few educated men who early in the last century did not believe that a boy who had to make his own way in the world would be best fitted for that hard task by spending the greater part of his school life in the study of dead languages. He was resolved to give his sons an opportunity of gaining for themselves a sound knowledge of at least one other living language besides English, and so the two boys went to school at Bruges. There they remained for four years and then only left on the outbreak of the revolution which ended in the separation of Belgium from Holland. It was at Bruges that Robert Barnes acquired that facility in the use of the French language which was so useful to him throughout his professional life and which, up to the time of his last illness, was a source of great pleasure to him. Young Barnes, on his return from Bruges, went to his father's home in Norwich and there continued his studies under a French refugee and a private tutor, John Thurgar. Later he read with George Borrow, the author of "The Bible in Spain." When 15 years of age Barnes was, after the manner of those days, articled to Richard Griffin, a surgeon practising in Norwich, who was one of the most prominent Poor-law reformers of his day and the founder of an Association of Poor-law Medical Officers When as a student of medicine Barnes came to London he entered upon his studies at University College. Thence he migrated to the Windmill-street School of Medicine, having been offered the joint posts of secretary to the school and house surgeon at Queen Adelaide's Lying-in Hospital. He served for two years at Queen Adelaide's Hospital and was also a student of St. George's Hospital.

Having become a Member of the Royal College of Surgeons of England, Barnes in 1842 went to Paris, where he arrived with £10 only in his pocket, and during his year of study there chiefly supported himself by his pen and by giving lessons in English. On his return to London he was an unsuccessful candidate for the post of resident physician at Bethlem Hospital—a defeat for which in later life he felt grateful. He could not afford to wait for practice and so he began work as a general practitioner at Notting Hill and there passed some years of his life. He, however, kept steadily in view his ambition which was to gain a post as lecturer in a London medical school. After holding one or two unimportant appointments he received the post of assistant obstetric physician to the London Hospital, and on the death of Dr. Ramsbotham a year or two later was promoted obstetric physician to that hospital. He was also soon elected physician to the Seamen's Hospital, the East London Hospital for Children, and the Royal Maternity Charity. St. Thomas's Hospital in 1862 invited Barnes to fill the office of obstetric physician and he migrated to that hospital from the London Hospital. A dozen years later he was appointed obstetric physician and lecturer at his old school, St. George's Hospital, and so he had the, perhaps unique, experience of having taught midwifery in three of the great London hospitals.

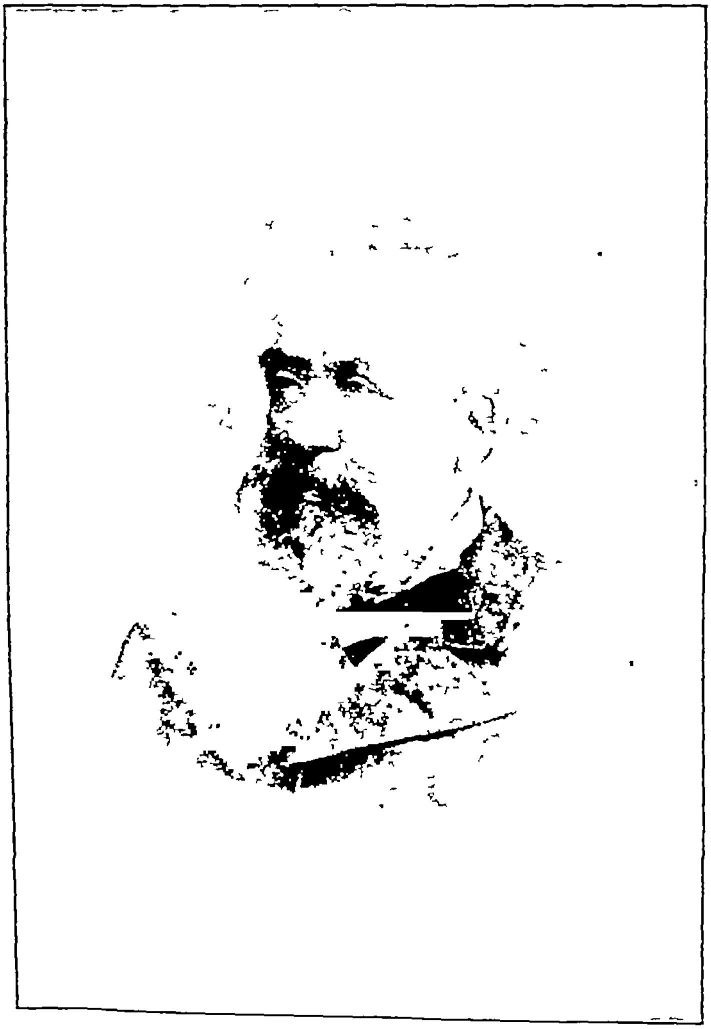
Barnes graduated M.D. Lond. in 1848, obtained the Membership of the Royal College of Physicians of London in 1853, and was elected Fellow of the College in 1857. He was a Fellow of many learned societies both in England and abroad, and in 1883 received the rare distinction of an Honorary Fellowship of the Royal College of Surgeons of England; but of all the honours offered to him he was proudest of the Honorary Fellowship which was conferred upon him by the Royal Medical and Chirurgical Society at its centenary celebration in 1905. He often spoke of the days in his early life when he was dependent in no small measure on his pen for his living. His connexion with the staff of THE LANCET in those days and for years afterwards was a pleasant memory to him, and he often dwelt on these experiences with satisfaction; indeed, he used to say that he owed much to the training of the intellectual faculties which writing for the press entailed upon him. There are few members of the staff of THE LANCET now living who actually were his collaborators in our columns, but the tradition of his work has been handed down to us, and it reports him as a remarkably clear, scholarly, and vigorous writer, determined to be fair but also determined not to let any squeamishness prevent him from telling the truth. Until the very end of his days Dr. Barnes would send us small notes on matters which he thought would interest our readers, and his communications always attracted notice. His contributions to medical literature both within and outside our columns were numerous and many of them of great value.

In the year 1847 he published in THE LANCET a Memoir on Placenta Prævia in which he first enunciated the views as to the pathology of this condition which he elaborated in his *Lettsomian Lectures* delivered before the Medical Society of London in the year 1857. In these lectures he pointed out very clearly and forcibly the important part played by the dilatation of the cervix in causing the separation of the placenta, and he advocated his well-known method of artificially separating the prævial portion of the placenta so as to arrest the hæmorrhage as soon as possible. This mode of treatment is still successfully practised by many obstetricians, although, in accordance with the modern practice of not introducing the hand into the uterine cavity if it can be avoided, it has to some extent been abandoned. A number of valuable contributions from his pen are to be found in the Transactions of the Obstetrical Society of London and in the pages of the medical journals. Amongst these we may allude to his papers on the following subjects—Induction of Premature Labour, Thrombosis and Embolism of Lying-in Women, Chorea in Pregnancy, Spondylolisthesis, Dysmenorrhœa, the Use of Perchloride of Iron in the Treatment of Post-partum Hæmorrhage, Intraperitoneal Hæmatocele, the Treatment of the Placenta in Cases of Extra-uterine Gestation, a Method of Suturing the Uterine and Abdominal Walls in Cæsarean Section, and the Use of the Forceps in Lingering Labour. The rubber hydrostatic dilators which bear his name, although they have been supplanted in recent years by the more useful and convenient Champétier de Ribes's bag, yet for a very long time formed a most helpful and safe means of procuring dilatation of the cervical canal. Barnes was also one of the chief advocates of the use of the long forceps in this country and he did much towards securing their acceptance by other obstetricians. His writings on the mechanism of labour, more especially with reference to Naegele's obliquity and the effect of the lumbo-sacral curve, are well known, and the advances which he made in the performance of the different operations for the delivery of the perforated head and in the carrying out of version are exemplified in the teaching of the present day. The two most important works published by Barnes were his "Lectures on Obstetric Operations" and his "Clinical History of the Medical and Surgical Diseases of Women." The former book is still a classic in the literature of obstetric medicine. It is one of the best and most practical books which have been written on this subject and it has served as a practical guide for thousands of medical practitioners. As Professor Pajot points out in his preface to the French translation, "the book is not a dogmatic treatise on the obstetric operations; it is a series of original lectures, comprising at the same time a practical analysis of the serious accidents of parturition, the indications for, and the manner of, operating, the method to choose, the instrument to prefer, and the details of the manœuvres required to insure success. The clearness of the style is perfect, and in fact all the questions of obstetrics are treated with accurate good sense. At each instant by some remark or other is seen revealed a superior mind ripened by having seen much and meditated much." The book contains a wealth of clinical material well analysed and digested, and we can only wish that it was read more widely than it appears to be at the present time. The work on the Diseases of Women is less well known and, indeed, is not so valuable a book. It contains, however, the result of a large experience and shows evidence of a very extensive knowledge of the literature of the subject. Dr. Barnes was the possessor of a happy style not only in his oral lectures but also in his writings; he could express himself forcibly and clearly and his large clinical experience rendered his opinions of great value. He stood out as a commanding personality amongst the teachers of his day, and much of his teaching may be found embodied in the practice advocated in modern text-books and founded as it was on accurate observations and correct deductions it need not fear the criticism of the future. He was a worthy follower of such men as Chamberlin, Smellie, Denman, Ramsbotham, and Simpson, and the historian of the English school of obstetric medicine will be compelled to pay much attention to the teaching and writings of Robert Barnes.

Dr. Barnes retired from consulting practice some 20 years ago and enjoyed during the long evening of his valuable life remarkable physical and mental health which in no small measure remained with him till February of this year, though in his later years he suffered from attacks of gout. When he was well over 80 years of age he suffered greatly from stone in the bladder, but after Mr. Buxton Browne crushed the stone his patient made a perfect recovery. It was not until this year that Dr. Barnes's health actually broke down. On Feb. 21st he awoke suffering from severe cramp in the left hand. As the pain continued he sent for Dr. H. Colgate who found evidences of thrombosis of the left brachial artery. In an hour or two there were symptoms of the same condition in the right arm. There was no loss of consciousness and Dr. Barnes calmly gave directions for the arrangement of his affairs. In 24 hours reappearance of pulsation in the affected vessels had set in and little by little there was a complete recovery of the circulation. The patient was not allowed to walk but was carried to his carriage and took daily drives, read, wrote letters, arranged his papers, and conducted business affairs. About three weeks before his death he had an attack of angina pectoris and suffered severely. The lungs became congested and œdematous. From this attack he rallied, again drove out, and tried to resume his usual occupations but this he could not do, his only complaint being that he felt unequal to his work. On May 11th there was plugging of the right femoral artery and on the following day plugging of the left popliteal artery, and soon afterwards, without evidence of suffering, he died.

Dr. Colgate of Eastbourne, who was his medical adviser and a friend of many years' standing, writes of Dr. Barnes: "As a mental exercise not only did he follow in the periodicals the progress of medicine but at the age of 85 he took up the study of Spanish and daily read Spanish books and papers. He also joined the Eastbourne Medical Society and was a frequent and interested attendant at the meetings. It was only during last summer that Dr. Barnes gave up his morning sea bath which he used keenly to enjoy. He walked down from his house to the shore, got into a boat, and when far enough from land dived from his boat and struck out vigorously. After his swim he sculled about for an hour or so, and then walked, sat in the sunshine, smoked a cigarette or two, and read the morning paper." A personal friend has sent us further details of Dr. Barnes's health which show that his brain was in good working order until last February, and even after that time his letters to our informant proved that he had a clear understanding of affairs, and that he made no mistake as to the meaning of the grave symptoms which had prostrated him on Feb. 21st. In the last of these letters—it was written on April 28th—Dr. Barnes said he could not hope again to visit London. It was his habit for many years to pay weekly visits to London for the purpose of attending the meetings of the board of directors of the Prudential Assurance Society. He often spent the night after these meetings in London and dined with the friend in question, "enjoying his dinner thoroughly, chatting about the events of the day and vigorously upholding his views touching matters political, about which he and his host were not always of the same opinion. After dinner he used to join his host's family in a rubber of whist. He was fond of the game and played it with great good humour. Indeed, a game of cards with people whom he knew well and liked was one of his pleasures and was a daily part of his family life. He regarded sixpenny points at whist as extravagant and detested what he deemed high stakes at any game."

From what we have said it is clear that the late Dr. Robert Barnes was a distinctly remarkable man, and he conformed to the rule that all men of strong personality are prone to strong likings and dislikings of their fellow men. Dr. Barnes had a strong personality and his likings and dislikings were very strongly marked. He was tenacious to a



ROBERT BARNES, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,
CONSULTING OBSTETRIC PHYSICIAN TO ST. GEORGE'S HOSPITAL.

high degree of any opinion which he had formed or adopted. Where his profession was concerned he was slow to approve or to condemn anything that was new to him, but if the subject interested him he carefully studied the new departure and formed his own opinion about it and from that opinion he was not easily turned. His judgment was sound and as a lecturer, or by the bedside, or in conversation, or in debate his expression of his views was given in clear and terse language. In defence and in attack Barnes often used very forcible words and sometimes what he said carried a sting with it which left where it struck a soreness of a far from transient kind. So, though very many men liked him and still more admired his ability, Barnes was not at all wanting in the making of enemies, a misfortune which sometimes turns to a man's profit and from which hardly any men of strong personality are free.

Dr. Barnes was twice married, first to Miss Eliza Fawkener, daughter of a London solicitor. By her he had three children, one son, Dr. R. S. Fancourt Barnes, and two daughters, one of whom is the wife of Dr. A. S. Newington of Ticehurst in Sussex. Some years after the death of his first wife Dr. Barnes married in 1880 Miss Alice Maria Hughes, daughter of Captain William Garnons Hughes, R.A., of Glancothy, Carmarthenshire, D.L., and J.P. for that county. Of the marriage there are two children, a son and a daughter.

At the funeral, which took place at Eastbourne on May 16th, the Royal College of Physicians of London was represented by Dr. Heron, the Royal Medical and Chirurgical Society by Mr. J. Y. W. MacAlister, and THE LANCET by Dr. J. G. Glover.

WILLIAM SEYMOUR BURROWS, J.P., B.A. CANTAB., M.R.C.S. ENG.

BY the death of Mr. W. Seymour Burrows, of Exton Mansions, Hove, Brighton loses one of its most familiar and interesting figures. His decease will be acutely felt by a large circle of friends and patients, many of whom regarded him almost as a brother rather than as an acquaintance. He was a true, kind, generous-hearted man, a firm friend, and a most genial and humorous companion. He was the son of the late Sir John Cordy Burrows, F.R.C.S., who in his day was one of the most respected and popular men in Brighton (*vide* THE LANCET, vol. i., p. 515 and p. 548, 1876) and who did great things for the town, was thrice mayor, was knighted, and was specially honoured by having a statue erected to his memory at the main entrance to the Pavilion Gardens. W. Seymour Burrows after his school life went to the University of Cambridge, where he graduated as B.A. in 1870; thence he went to St. George's Hospital and took the diploma of M.R C.S. Eng. in 1875. He then joined his father in general practice at the old house in the Old Steine, and there he resided until quite recently, when the noise caused by the new tramcars forced him reluctantly to leave his old home and to seek a more quiet spot. Apart from his professional practice, which was large and influential, he found time for many and various pursuits. He early in life took an active interest in the Volunteer movement and this interest was maintained until within a year or two of his death. He attained the rank of Surgeon-Lieutenant-Colonel and he was one of the first to receive the decoration of "V.D." His name will perhaps be best remembered in connexion with the amount of good work which he did for the town as a trustee of the race stand. He succeeded his father as a trustee and for many years he and Alderman Abbey, J.P., were the sole trustees. As a result of their careful management the town received many munificent gifts, amongst them being what is known as the Tenantry Down, also the Queen's Park, while a large sum—some £3000 or £4000—was left to the town to be invested and the interest applied at Christmas time on behalf of the aged and deserving poor. As an outcome of all this good work the corporation as a mark of its high esteem and gratitude at a banquet presented Mr. Seymour Burrows with a beautiful illuminated address and a most valuable and handsome silver salver. He was an ardent Freemason. He was a member of the Yarborough Lodge, of which lodge he was Worshipful Master in 1887. Among other prominent distinctions he was Past Provincial Junior Grand Deacon for Sussex.

For some years past Mr. Seymour Burrows had not been in robust health and during the past year it was only too obvious to his friends that his health was fast failing, though he was not confined to his house until the last two or three weeks of his illness. The end came on May 8th when he died suddenly from heart failure. He was aged 58 years. The body was cremated at Golder's Green on May 10th and the interment of the ashes in the family vault took place on the following day. The funeral was attended by a large assembly of old patients and friends and representatives were present of the Masonic and other institutions to which he belonged.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. W. C. Glasgow, formerly professor of laryngology in Washington.—Dr. George Gabrichevski, founder of the Moscow Bacteriological Institute.—Dr. C. Féré of the Bicêtre Hospital, Paris.—Dr. Hugo Magnus, extraordinary professor of ophthalmology in the University of Breslau. His writings include not only ophthalmological subjects but many papers on the history of medicine.—Dr. Hugo Beckmann, a Berlin laryngologist, at the age of 46 years.—Dr. Ferdinand Klug, *privat-docent* of otology in the University of Budapest.—Dr. Anton Bleichsteiner, professor of odontology in Prague.—Dr. Ashbel P. Grinnell, formerly professor of medicine in the University of Vermont.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination for the Licence in Dental Surgery the following gentlemen were approved in the subjects indicated:—

Mechanical Dentistry and Dental Metallurgy.—Stammers Henry Alabaster, Royal Dental Hospital; Herbert Stuart Blackmore, Royal Dental Hospital; Frank Bocquet Bull, Guy's Hospital; Victor Charles Burt, Royal Dental Hospital; Percivale James Burton, University College, Bristol; Norman Sambell Cardell, Liverpool University; Stephen Wilson Charles, Guy's Hospital; Abraham Cohen, Guy's Hospital; Robert Morris Colwill, Royal Dental Hospital; Arthur Ernest Conway, National Dental Hospital; Leonard Marshall Crockett, Royal Dental Hospital; George Leslie Curnock, Royal Dental Hospital; Hubert Daw, Guy's Hospital; Walter Edmund Drummond, University College, Bristol; William Henry Edmonds, Guy's Hospital; Ernest William Frank Falkner, Liverpool University; George Frederick Fawn, University College, Bristol; Linton Albert Ramsey Fennell, Royal Dental Hospital; John Daniel George, Guy's Hospital; Henry Vincent Gibbons, Guy's Hospital; John Ferguson Gow, Royal Dental Hospital; Leonard Beard Griffin, Guy's Hospital; Louis François Guanziroli, Charing Cross Hospital and Royal Dental Hospital; Henry Hall, Royal Dental Hospital; Claud Noel Hardman, Sheffield University; Newcome Herbert Harrison, Royal Dental Hospital; Percy Samuel Harrison, Guy's Hospital; John Percival Helliwell, Manchester University; Louis Edwin Hitchcock, National Dental Hospital; Ernest Alfred Sebastian Hoare, Royal Dental Hospital; William Archer Hodgson, Guy's Hospital; Ivor Robert Hudleston, University College, Bristol; Percy Stanley Humm, Guy's Hospital; William Alfred James, Guy's Hospital; Gordon Johnson, Royal Dental Hospital; William Joseph Kennealy, Guy's Hospital; William Stocks Lacey, Guy's Hospital; John Vollans Lambert, Royal Dental Hospital; Linthall Harry Leatherby, Royal Dental Hospital; Frank Augustus Lowe, Guy's Hospital; James Norman McNaught, Liverpool University; Douglas John Marr, M.B., Ch.B. Aberdeen, Royal Dental Hospital; Ainslie Palk Marsh, Guy's Hospital; Harold Matthews Meek, Manchester University; Jamshedji Jivanji Modi, L.M. & S. Bombay, Bombay University and Royal Dental Hospital; Reginald Charles Morgan, Guy's Hospital; Robert William Morrell, Guy's Hospital; Alfred Bunce Plank, Liverpool University; Roland Thomas Pounds, Royal Dental Hospital; Harold William Read, M.R.C.S., L.R.C.P., Royal Dental Hospital; Augustus John Reynolds, Guy's Hospital; John Roberts, Guy's Hospital; Sydney Shovelton, Birmingham University; Edgar Smith, Guy's Hospital; Edgar Eaton Solomon, Guy's Hospital; Harold Gordon Spain, Guy's Hospital; Eric Le Masurier Spurgeon, Royal Dental Hospital; Dudley Bayzand Tasker, Guy's Hospital, William Edgar Antonius Tibbalds, Guy's Hospital; Edgar Arthur Tomes, Guy's Hospital; Arthur George Trott, Royal Dental Hospital; Augustus Vallack Wallis, Royal Dental Hospital; Joseph Jackson Wardill, Royal Dental Hospital; Alexander MacDonald Watson, Guy's Hospital; Walter Ernest Watson, Guy's Hospital; Walter William Whittington, Royal Dental Hospital; and George Kerry Wild, Birmingham University.

Mechanical Dentistry.—William Percy Charles Ashdown, National Dental Hospital; Malcolm Barker, Royal Dental Hospital; Robert Hope, Harvard University and Guy's Hospital; Doric Yvon Hylton, Guy's Hospital; Alfred Samuel, Guy's Hospital; and Albert John Schaefer, Guy's Hospital.

Dental Metallurgy.—Oswald Roy Allison, Manchester University; Thomas Percy Brown, Birmingham University; Neville Dutton Clarke, Guy's Hospital; Norman Malcolm McArthur Douglas, Liverpool University; Frank Harold Edey, Guy's Hospital; Edward Inglis Hall, Royal Dental Hospital; John Wilfrid Hall, Guy's Hospital; Henry Stanley Pugh, Guy's Hospital; Stanley Alfred Riddett, Royal Dental Hospital; William Sherritt, Sheffield University; Stanley Runton Storey, Royal Dental Hospital; and James Roy Williams, Manchester University.

UNIVERSITY OF CAMBRIDGE.—Courses will be given during the Long Vacation, commencing on July 4th, in elementary physiology, osteology, histology, practical physiology, topographical anatomy, and dissections. The first, second, and third (Part I.) examinations for the M.B. and B.C. degrees will begin on June 10th. Names and certificates of candidates must reach the registrar by June 4th.—At the congregation on May 9th the following degrees were conferred:—

M.D.—D. W. Carr and G. W. Micklethwait, Trinity.
Sc.D.—H. H. W. Pearson, Caius.
M.B.—W. L. Murphy, St. John's.
B.C.—W. E. Lee and J. H. Pratt, Trinity; R. R. Walker, St John's; A. R. Jordan, Clare; S. P. Chan and R. G. Markham, Caius; H. J. Fardon, Christ's; and R. B. Lloyd and J. H. B. Martin, Emmanuel.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—The electors will shortly proceed to elect a Sharpey Physiological Scholar in place of Dr. J. M. Hamill who has resigned. The scholar will receive a sum of £150 a year. Candidates must have attended one or more classes in the Faculty of Medical Sciences or of Science in the College. As the purpose of the scholarship is to give those who intend to qualify themselves for physiological or pathological work, whether as teachers or investigators, the opportunity of acquiring the requisite knowledge and skill, the holder of the scholarship is expected to devote his whole time to his duties in the laboratory. Under the terms of the endowment the Sharpey Scholar is required to assist throughout the session in the teaching of the students in the class of practical physiology and will, if required, aid the professor of physiology in the conduct of physiological inquiries. The appointment of the scholarship will be for one year but the holder of the scholarship is eligible for re-election. Full particulars of the scholarship can be obtained on application to the secretary of the College or to Professor E. H. Starling. Applications should be made by letter only to Walter W. Setton, M.A., secretary, on or before June 16th.

SOCIETY OF ARTS.—Medical questions of public interest, capable of being adequately presented in some of their aspects to a non-professional audience, occasionally form the subject of papers read before the Society of Arts. Sleeping sickness has recently received much attention from governments and administrators owing to the enormous loss of life which it has caused in Equatorial Africa and the possibility that it may spread into other tropical countries. The earliest record of it was made in 1803 by Dr. Thomas Masterman Winterbottom who observed it among natives of Africa in the neighbourhood of Sierra Leone. Most of Dr. Winterbottom's life was spent at South Shields where he died on July 8th, 1859, at the age of 94 years. He was the oldest medical man registered under the Medical Act of 1858. On May 15th a paper entitled "Trypanosomiasis or Sleeping Sickness" was read at a meeting of the Society of Arts by Dr. Herbert W. G. Macleod. He said that the disease was endemic in Equatorial Africa. On the coast line it extended from the Senegal river in the north to Loanda in Portuguese West Africa in the south. It was also met with as far inland as the Victoria Nyanza and Albert Nyanza, and the regions adjoining the rivers Senegal, Niger, Congo, and Nile were specially affected. It was known that in the valley of the Congo from 400,000 to 600,000 deaths from this cause have occurred during the last ten years, and in Uganda alone the mortality has reached from 40,000 to 50,000. The trypanosome or organism which caused the disease consisted of protoplasm, was single-celled, had an elongated irregular shape, and was pointed at each end. It possessed a nucleus and nucleolus distinct from one another and a peculiar wavy line known as the "undulating membrane," which commenced in the nucleolus at one extremity and terminated at the other end in a fine thread or flagellum. This acted as a propelling organ and by lashing movements the trypanosome swam about in the blood stream—a worm-like organism wriggling actively among the blood corpuscles. In length it was somewhat greater and in breadth it was somewhat less than the diameter of a red blood corpuscle. It never penetrated into a corpuscle, as the organism of malaria did. It could be cultivated outside the body in agar jelly containing human blood. It reproduced itself by longitudinal division. The disease was communicated from one person to another by a blood-sucking insect, the glossina palpalis, a variety of the tsetse fly, which by feeding first on the blood of an infected person and then on the blood of a non-infected person conveyed the trypanosome from the former to the latter. It was believed that the fly did not continue to be infective for longer than 48 hours, or at most three days, after sucking infected blood. The length of glossina palpalis from the tip of the proboscis to the end of the closed wings was about half an inch. Dr. Macleod described the morphology and development of several species of glossina at considerable length, and specimens of the insects in glass tubes were handed round for inspection. With regard to the symptoms of the disease he said that it was not possible to tell how long a person might remain infected without showing any signs of the malady. This latent stage might extend over a year or more; or the signs of illness might be so indefinite that suspicion was not aroused. The first symptom that attracted notice was an enlargement of the glands in the neck. From these glands the trypanosome might be obtained. Nervous symptoms subsequently appeared, such as great lassitude and lethargy, accompanied by emaciation. The sleepy condition did not always make its appearance; heavy sleep was symptomatic in a comparatively small number of cases and in every instance its presence indicated the terminal stage of the disease. So far as was known, attacks attended by definite symptoms of the disease were always fatal. Recently atoxyl has been administered and a few patients have apparently benefited under its use; it was still under trial. Dr. Macleod incidentally made some short references to diseases produced by trypanosomata in the lower animals. He said that in India Evans first discovered a trypanosome in 1880 which caused the disease known as surra in horses and cattle; this disease was communicated by the bite of a blood-sucking fly. The tsetse-fly disease (known as nagana) among horses in South Africa was another example. He also gave an outline of the discovery of the trypanosome of sleeping sickness, mentioning the names of Forde, Dutton, Castellani, Bruce, and others.

THE ABUSE OF COCAINE.—Within the past five years (writes the British Consul at Baltimore, U.S.A.) the excessive indulgence in cocaine by the poorer people, and especially by the negroes, has increased enormously, bringing with it its usual demoralisation and degradation, as well as, according to some observers, an increase in the death-rate among the negro population. The Health Commissioner, however, is not of that opinion: he attributes the high mortality in that race to consumption principally. The evil became so apparent, especially in the police courts, where it was estimated that 70 per cent. of the prisoners were users of the drug, that the Maryland legislature passed a law in 1906 prohibiting the sale of it in any quantity, either in a pure state or combined with other articles unless prescribed by a medical man. The penalty for violation of the law is a fine of not less than £5 or more than £10 for the first offence, and for the second offence from £10 to £20, whilst for the third offence the offender may be fined from £20 to £40, with the addition of not more than 60 days' imprisonment and the forfeiture, should the offender be a druggist, of the pharmacist's licence. It is said by the police that the law has had little effect in breaking up the traffic, because of the inadequate punishment imposed by it and that to make it operative the first offence should be punished by imprisonment. The profits on the sale of the drug are so enormous that the imposition of a fine is thought little of in the way of punishment by the vendor of it.

CLIMATE OF SAN DIEGO.—Mr. Hutchinson, British Vice-Consul, writes that the great asset of San Diego is its climate. Occupying the extreme south-west corner of the United States, with an extent of country reaching eastward along the Mexican border as far as the Colorado River, it contains within its borders almost every condition of climate, from desert heat and cool mountain altitudes to the most equable climate in the world on the Pacific coast, where San Diego is situated. The cool sea breeze which blows through the summer months keeps the temperature down, with a very few exceptions, below 80° F., while the winter is remarkable for sunshine and warm weather. In the words of a former Vice Consul, "San Diego has long been recognised as having the best climate in the United States, and it is increasingly becoming a resort for invalids and persons of means desiring a pleasant residence free from extremes of heat or cold, from malarial influences, and from storms. It is represented by travellers and physicians from personal experience, as well as study of the climatic records of the various places, that the climate of San Diego is preferable to that of any part of the Riviera or any other European resort." The statistics of the weather bureau for

1906 show: highest temperature (Sept. 31st), 91°; lowest temperature (Jan. 1st), 35°; number of days above 80°, 11; number of days below 40°, 4; seasonal rainfall, from September, 1905, to September, 1906, 14·62 inches.

CONVALESCENT HOMES ASSOCIATION.—The second annual meeting of the Convalescent Homes Association was held last week at the office, 32, Sackville-street, London, W., Sir William S. Church being in the chair. The annual report, which was received and adopted, stated that the second annual report of the Convalescent Homes Association presented a record of satisfactory progress. A few years ago it was represented that the needs of the metropolitan hospitals for the convalescent treatment of patients requiring more surgical attention than was generally afforded by convalescent homes were not fully supplied. A few persons well acquainted with the needs of hospitals and conversant with the working of many of the convalescent homes considered that if the hospitals and convalescent homes could be *brought more closely together* a number of beds could, at small additional expense, be made available for these patients without having to expend large sums of money in providing new buildings for their reception. As an outcome of their efforts the present association was established two years ago. This year a number of special surgical beds have become available without any appeal for monetary assistance from the public—viz., 20 beds, ten for men and ten for women—at the Bexhill Homes of the Metropolitan Convalescent Institute, opened in June, 1906; nine at Mrs. Gladstone's home for men and boys; six at the Baroness de Hirsch's home for the Jews, in July, 1906, together with some previously opened. In face of the alleged urgent need for further provision for convalescents recovering from operations it is a striking fact that these new surgical beds are not yet fully occupied. One reason may perhaps be that very few of them are free and that the hospital Samaritan funds are not able to support the expense. At the same time, it is believed that were the matter more widely known to the medical profession as well as to the public there would be no lack of applicants for the beds. During the year a list of "frequent inmates and undesirables" had been compiled for private circulation among members. There had been an increasing number of applications for information from the public, and though these were still few it is hoped that when more widely known the association will increase its sphere of usefulness. The membership of the Convalescent Homes Association now includes six hospitals and 16 convalescent institutions, representing 19 homes.

THE MACCABÆANS.—A medical dinner was given by "The Maccabæans" on May 22nd at the Wharncliffe Rooms, Hotel Great Central, London, Dr. Bertram L. Abrahams being in the chair. The list of guests included Professor T. Clifford Allbutt, Dr. W. H. Allchin, Sir William S. Church, Sir Anderson Critchett, Mr. F. S. Eve, Dr. F. de Havilland Hall, Surgeon-General Sir Alfred H. Keogh, Dr. Donald MacAlister, Professor Howard Marsh, Mr. Henry Morris, Sir Shirley F. Murphy, Sir Richard Douglas Powell, Mr. C. Stonham, Dr. James Taylor, Sir Frederick Treves, Sir John Batty Tuke, and Sir John Tweedy. The toast of the evening, "The Medical Profession," was proposed by the chairman, who stated that he had sent a telegram to Lord Lister, communicating to him the respectful salutation of the Society of Maccabæans, to which Lord Lister replied with a telegram of thanks. The chairman described the aims and objects of the Maccabæans, a society of Jews who follow professional pursuits, which had its origin in Mr. Zangwill's "Bachelors' Club," but which has developed into an important social organisation. He said that the reason for the dinner was the obvious one of desiring to honour medicine, a science to which every guest present had contributed. Sir R. Douglas Powell, in replying, said he was convinced that when the report of the Royal Commission on Vivisection now sitting was issued it would clear away the false ideas and refute the misstatements which had been long current in regard to the humanity of medical men. Mr. Morris, who also replied, gave some interesting details concerning the code of Hammurabi which dated back to 2150 B.C. This code regulated the fees paid to surgeons and ordained that should a patient die after an operation the surgeon should have both his hands cut off. After Sir J. Batty Tuke had also acknowledged the toast, the President of the Maccabæans, Mr. M. H. Spielmann, the well-known art critic, proposed the toast of "The Guests" in a brilliant speech crowded with happy allusions and humorous citations. This toast was acknowledged by Sir Frederick Treves, who thought that surgical measures should be taken for the extinction of after-dinner speakers; by Sir Alfred Keogh, who showed how much the Army Medical Service and all our public services owe to the teachers of medicine and regretted the absence of any recognition on the part of the public of that debt; and Dr. MacAlister, who referred in a brief but interesting speech to the discovery in Palestine of the remains of the palace of Simon Maccabæus. Sir John Tweedy, in submitting the toast of "The Chairman," said that Dr. Abrahams had been one of his pupils, whose successful career he had watched with great interest. After the chairman had made a suitable reply the proceedings concluded.

CONFERENCE OF CHARITY ORGANISATION SOCIETIES.—From July 3rd to 6th inclusive there will be held at the Thatched Assembly Rooms, All Saints' Green, Norwich, a conference of charity organisation societies. In the evening of June 3rd a reception will be held and the real work of the congress will commence on June 4th. A paper on Provident Medical Associations will be read. A discussion on this subject will be opened by Dr. Michael Beverley (Norwich). In the evening there will be a public meeting to discuss the subject of Skilled Employment Committees. On the morning of June 5th the Lord Bishop of Norwich will preside at a public meeting at which "The Work of the School of Sociology" will be discussed and in the evening Dr. W. B. Knobel, honorary secretary of the Malvern Charity Organisation Society, will read a paper on "Preventive Measures and Home Treatment for Consumption." Dr. F. W. Burton-Fanning will open the discussion. A private meeting will be held on the morning of June 6th, the subject of discussion by delegates being "Thrift Work in the Past Year." Various excursions and social arrangements have been organised for the entertainment of visitors during the Congress and a visit will be made to Kelling Sanatorium on the afternoon of June 5th. Full particulars can be obtained at the rooms in which the conference will be held.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Whitsuntide Holidays.

BOTH Houses of Parliament adjourned on Thursday, May 16th, for the Whitsuntide recess. The House of Commons has taken a short holiday, reassembling on Thursday, May 23rd. The holidays of the House of Lords extend to Tuesday, May 28th.

Medical and Dental Companies.

The Select Committee of the House of Lords which is to take evidence on the subjects dealt with in the Prohibition of Medical Practice by Companies Bill and the Dental Companies (Restrictions of Practice) Bill has now been nominated. The five peers who will compose the committee are Viscount FALKLAND, Viscount KNUTSFORD, Lord HYLTON, Lord LUDLOW, and Lord COLEBROOK. They are to appoint their own chairman.

The Royal College of Physicians of London and the Plague.

On the motion of Dr. RUTHERFORD a return has been granted of the Memorandum of the Royal College of Physicians of London in May, 1905, on plague.

The Public Health Bill.

The Public Health Bill has been read a second time in the House of Commons. It was allowed to pass this stage at the time of unopposed business.

Notification of Births in Glasgow.

A Select Committee of the House of Lords, over which the Earl of CAMPERDOWN presided, has just passed certain clauses in the Glasgow Corporation Bill, which provide for the notification of births in that city in a manner somewhat similar to that which prevails in Huddersfield. The provision in the Glasgow Bill lays down the principle of notification of births within 48 hours of their occurrence. Dr. A. K. CHALMERS, the medical officer of the city, supported the clause in the evidence which he tendered to the committee on the ground that they would assist in checking the high rate of infantile mortality prevalent in Glasgow. The provisions, he mentioned, would be in force for five years only. The CHAIRMAN put the question to him whether the period of notification could not be extended to three days without impairing the utility of the proposal. Dr. CHALMERS replied that he would prefer the notification within 48 hours, as such a provision would better assist in coping with the problem of infantile mortality.

Accordingly the committee left the period of notification at 48 hours. The Bill, which deals with a variety of subjects, has still to pass through all its stages in the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, MAY 15TH.

The Mortality from the Plague.

Dr. RUTHERFORD asked the Secretary of State for India the number of deaths from plague in India during April, 1907, and the total number from September, 1896.—Mr. MORLEY replied: The figures are for April, 1907, deaths from plague 314,000; from September, 1896, to end of April, 1907, 5,326,000 approximately.

The Board of Education and a Medical Department.

Mr. WEDGWOOD asked the President of the Board of Education what immediate steps he proposed to take with a view to obtaining expert opinion as to the advisability of establishing a permanent medical department at the Board of Education, seeing that this matter was not considered by the Inter-Departmental Committee on Medical Inspection two years ago and seeing that no information concerning any other expert advice was available for consideration by this House.—Mr. MCKENNA answered: I can assure my honourable friend that experts have not failed to give me the great advantage of their advice upon this question. The opinions which I have received from them are by no means wanting in variety.

The Payment of Vaccination Officers.

Sir WILLIAM BULL asked the President of the Local Government Board whether he would make provision by a vaccination order for the payment of a fee to the vaccination officer for registering the certificates proposed in his Bill or abolish the payments by fee to the vaccination officer and provide for him to receive a fixed income based upon his average income for the five years previous to the Bill becoming law.—Mr. JOHN BURNS furnished the following written answer: I am not aware of any sufficient reason for adopting the course suggested.

The Construction of Poor-law Infirmaries.

Sir WILLIAM BULL asked the President of the Local Government Board whether the Board some years ago issued a code of suggestions and instructions for the guidance of boards of guardians as to the mode of constructing workhouses and infirmaries for Poor-law purposes; what was the date of the last edition of the code; and whether, in that code or in any other official publication, any suggestions had been issued for the guidance of guardians as to the best mode of equipping these institutions with electricity for lighting and power purposes.—Mr. JOHN BURNS replied (by written answer): The Board some years ago issued a memorandum as to the points to be attended to in the construction of workhouse buildings, and extracts from it with certain alterations have continued to be issued. The last material alterations were made in 1897. A memorandum on the construction of Poor-law infirmaries was issued in October last. The answer to the last part of the question is in the negative.

THURSDAY, MAY 16TH.

The Medical Inspection of Schools.

Mr. G. H. ROBERTS, on behalf of Mr. RAMSAY MACDONALD, asked the President of the Board of Education whether his attention had been called to the evidence given before the Departmental Committee on the medical inspection of school children, showing that the existing methods of inspection, as conducted by the local educational authorities in England, lacked uniformity and coördination, and were in many instances of little value; and whether he proposed to issue, for the guidance of these authorities and their inspectors, a memorandum of suggestions and make a request for annual reports under certain specific headings to test the adequacy of the inspection.—Mr. MCKENNA replied: I think there can be no doubt that when the Administrative Provisions Bill becomes law some guidance and advice from the Board of Education as to the methods of inspection and the classification of results will be necessary. How to secure the maximum of advantage from a general system of medical inspection consistently with securing the smooth working of the scheme and the coöperation of the local authorities is a matter which requires, and is receiving, careful consideration; but I am not yet in a position to make any statement.

The Medical Advisers to the Board of Education.

Mr. ROBERTS further, on behalf of Mr. MACDONALD, asked the President of the Board of Education in what capacity the two medical men were attached to the Board of Education; and whether he proposed to assign to them definite medical duties and to make them directly responsible to himself and not to the permanent head of the department.—Mr. MCKENNA answered: The two officers in question hold the post of His Majesty's Inspector of Schools and it is mainly on their advice that the Board acts in dealing with schools for afflicted children and other matters where technical medical knowledge is especially necessary. I see no reason for introducing such an innovation in the organisation of a Government department as my honourable friend suggests in the last paragraph of his question.

Public Abattoirs in Scotland.

Mr. WATT asked the Secretary for Scotland whether his attention had been called to the unanimous recommendation of the Convention of Royal Burghs of Scotland that private slaughter-houses should be abolished and public abattoirs substituted, and whether he would take steps, in view of that recommendation, to carry out the suggestion.—Mr. SHAW (who answered for Mr. SINCLAIR) said: When the inquiry in progress is completed the recommendation referred to by my honourable friend will receive careful consideration.

The Inspection of Irish Pork.

Mr. WATT asked the Secretary for Scotland whether he would see that all carcasses of swine slaughtered in Ireland for export to Scotland were inspected in accordance with the recommendation of the Local Government Board—namely, that the presence of tuberculous deposit in any degree should involve seizure of the whole carcass and organs; and, if the carcasses and organs could not be inspected by competent inspectors in Ireland, whether he would take steps to prevent the flesh being sold in Scotland for human food.—Mr. SHAW (the Lord Advocate) answered: With regard to the first part of my honourable friend's question I must ask him to apply to the Chief Secretary for Ireland. With regard to the second part it is not proposed to alter the system established by the Public Health Act, 1897.

Seizures of Meat in Glasgow.

Mr. WATT asked the Secretary for Scotland whether his attention had been called to the fact that on Feb. 18th and 20th last forelegs of chilled beef were seized in Glasgow Meat Market on the stance of the agent of one of the largest meat exporters in the United States; that these forelegs were stamped U.S. Inspected and passed; that they showed tuberculous nodules and on incision glandular invasion; and whether he would say what steps the Local Government Board had taken to prevent importation of meat in such condition into Scotland. —Mr. SHAW replied: I have received no official information with regard to the facts mentioned by my honourable friend. The Local Government Board for Scotland has no power to prevent the importation of meat from any country. The present system of inspection authorised by Section 43 of the Public Health Act, 1897, is, if properly administered, sufficient to protect the consumer of foreign meat, as is shown by the seizure of the meat in the case referred to.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

BECK, E. A. A., M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Bromyard District of the county of Hereford.

CHARLES, HERBERT, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Anæsthetist to the Middlesex Hospital.

CLEARY, M., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Newport District of the county of Mayo.

DOLAMORE, W. H., M.R.C.S., L.R.C.P., L.D.S. Eng., has been appointed Lecturer on Operative Dental Surgery at the Royal Dental Hospital of London, Leicester-square, W.C.

FINDLAY, W. D., M.B., C.M. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Middleton District of the county of Lancaster.

GELLATLY, ANDREW, M.B., C.M. Edin., has been appointed Medical Officer of Health of Droylsden, Manchester.

HARRIS, JOHN HENRY, M.D. Durh., M.R.C.S., L.S.A., D.P.H. Camb., has been reappointed Medical Officer of Health for the Dartmouth and Totnes Port Sanitary Authority.

HIBBERT, J. COOTE, M.D. Lond., D.P.H., has been appointed Medical Officer of Health of the Borough of Warrington.

LOGAN, W. A., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

STANTON, A. T., M.D. Toronto, M.R.C.S., L.R.C.P. Lond., has been appointed Second Assistant at the Kuala Lumpur Laboratory, Straits Settlements.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ALNWICK INFIRMARY.—House Surgeon, unmarried. Salary £140 per annum, with apartments, attendance, &c.

BETHLEM HOSPITAL.—Two Resident House Physicians (unmarried) for six months. Salary £50, with apartments, board, and washing.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, John Bright-street, Birmingham.—Clinical Assistant. Honorarium at rate of 52 guineas per annum.

BIRMINGHAM, UNIVERSITY OF.—Lectureship in Dental Histology and Pathology.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100.

BRADFORD ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Assistant Resident Medical Officer for three months. Honorarium of 25 guineas, with board and washing.

BURY ST. EDMUNDS, WEST SUFFOLK GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Physician for six months. Salary £30, with board, residence, and laundry.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 a year, with board, apartments, and laundress.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary £120 per annum, with board, &c. Also Surgeon and Physician to the Out-patients.

COLCHESTER, ESSEX AND COLCHESTER GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

Devonport, Royal Albert Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, board, &c.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £25 per annum, with board and washing.

Egypt.—Sub-Inspector of Ophthalmic Hospitals, unmarried. Salary £500 a year.

French Hospital, 172, Shaftesbury-avenue, London.—Second Resident Medical Officer. Salary £50.

Great Yarmouth Hospital.—House Surgeon. Salary £90 per annum, with board, lodging, and washing.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence. Also Anæsthetist.

Hull, Royal Infirmary.—Honorary Assistant Surgeon to Out-patients.

Ipswich, East Suffolk and Ipswich Hospital.—Third House Surgeon. Salary £50 per annum, with board, attendance, and washing.

Leeds In-door Institutions, Beckett-street—Assistant Medical Officer. Salary £100 per annum, with board, washing, apartments, and attendance.

Liscard, near Liverpool, Victoria Central Hospital.—Honorary Aurist and Laryngologist.

Liverpool Stanley Hospital.—Junior House Surgeon. Salary £60 per annum, with board, residence, and washing.

London Temperance Hospital, Hampstead-road, N.W.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing.

Maidstone, West Kent General Hospital.—Assistant House Surgeon and Anæsthetist, unmarried. Salary £60, with board, lodging, and washing.

Macclesfield General Infirmary.—Junior House Surgeon. Salary £60 per annum, with board and residence.

Manchester Eye and Ear *Hospital*, 25, St. John-street.—Honorary Assistant Aural Surgeon.

Middlesbrough, North Ormesby *Hospital*.—House Surgeon. Salary £120, with apartments and board.

Newcastle-upon-Tyne, City and County *of*.—*Assistant Medical* Officer of Health and Resident Medical Officer of the City Hospital for Infectious Diseases, unmarried. Salary £300 per annum, with board, lodging, &c.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160.

Newport and Monmouthshire *Hospital*.—Junior Resident Medical *Officer*. Salary *£70* per annum, with board, residence, and laundry.

Queen *Adelaide's Dispensary*, Pollard-row, Bethnal Green-road, E.—Honorary Surgeon.

Rochdale Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

Royal Ear Hospital, Dean-street, Soho, W.—House Surgeon for six months. Salary at rate of £40 per annum.

Saint Leonard, Shoreditch, Infirmary, 204, Hoxton-street, N.—Second Assistant Medical Officer. Salary £100 per annum, with rations, washing, and apartments.

St. Bartholomew's Hospital.—Lectureship in Anatomy.

St. Thomas's Hospital.—Assistant Physician.

Throat Hospital, Golden-square, W.—House Surgeon. Salary at rate of £75 per annum, with residence, board, and laundry.

Walsall *and District Hospital*.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

West Bromwich District Hospital.—*Resident Assistant House* Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing. Also Senior House *Surgeon, unmarried*. Salary £110 per annum, with board, residence, and washing.

West Ham Hospital, Stratford, E.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, residence, &c.

West London *Hospital*, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry allowance provided.

Worcester General Infirmary.—House Physician. Salary £80 per annum, with board and residence.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Wolston, in the county of Warwick; at Duleek, in the county of Meath; at Stornoway, in the county of Ross; at Stafford, in the *county of Stafford*; at Grantham, in the county of Lincoln; and at Tenbury, in the county of Worcester.

Births, Marriages, and Deaths.

BIRTHS.

Hinds.—On May 20th, at Bridge House, Bexley, Kent, the wife of Thomas W. Hinds, M.D., of a daughter.

Low.—On May 20th, at 146, Harley-street, W., the wife of V. Warren Low, M.D., B.S., F.R.C.S., of a son.

DEATHS.

Armstrong.—On May 10th, at Weston-super-Mare, Surgeon-Major Lancelot Armstrong, late Army Medical Staff, aged 77 years.

Fayrer.—On May 21st, at Falmouth, Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I., LL.D., M.D., F.R.S., K.H.P., Physician Extraordinary to the King, in his 83rd year.

Owen.—On 15th inst., of post influenzal disease of the heart, Annie Laura, wife of Edmund Owen, F.R.C.S., in her 45th year. (Cremated at Golder's Green 21st inst.)

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE ART OF ADVERTISING.

Commissions, otherwise known as "palm oil" or "graft," are not unknown in this country as the recent example of West Ham shows. But our brothers in blood on the other side of the Atlantic are certainly far ahead of us in their outspoken version of the *proverb*, "You scratch my back and I'll scratch yours." We have received an affectionate epistle from the Ambulatory Pneumatic Splint Mfg. Co. of Chicago commencing, "My dear Doctor" and setting forth in simple language the advantages which we may expect if we do as the Co. desires us. The circular continues:—

> It is a privilege both to yourself and your patient, when you have a case to which this splint is suited, to tell such patient frankly that it is *his duty to himself* in order that you may get the best results for him, that he should take your recommendation of it and buy one, *through you*, for your use in his case: explaining to him, that we sell it only to the attending physician, who in most instances, of course, requires the patient to advance the cash necessary to procure it.
>
> There is nothing in the book that you can't show him. The photographs will arouse his interest and induce him to willingly purchase the splint for his own use and benefit.
>
> You may charge the patient the prices that are quoted in the book, if you require him to make a purchase. We make the prices the same to you as though you were buying it for your own use and herein name our physician's prices.

The physician's prices, we note, on reference to the book, are for the splint with the shoe 34 dollars instead of 40, with varying reductions on "extra parts." The most delightful portion of the circular is the following:—

> In many instances the patient buys the splint; when he is well, as he scarcely ever hopes for a future use of it, he donates the splint to his physician, in excess of paying his doctor's bill, if he is of a liberal and grateful turn.
>
> On the other hand, many surgeons purchase the splint on their own account and hold and rent it to respective patients, who require its use. This, however, is a matter between you and the patient.

Obviously, when the grateful patient has "donated" the splint to his physician, the physician can rent it to another patient and so make a bit more. And what is this wonderful splint? So far as we can understand from the book it is simply the well-known Thomas's splint, with an inflatable ring at the top and with the side rods made capable of extension. There are four rods instead of two, or perhaps we should say eight rods, for they slide on one another in the fashion of a trombone slide. Thus extension can be made. Whatever may happen in America, we do not think that the Ambulatory Pneumatic Splint Mfg. Co. will get many orders here, for although the splint is probably a good one the method of recommending it is most unsatisfactory.

"LEONARD DE BAYER."

To the Editors of The Lancet.

Sirs,—I beg to inform you that I hold a warrant for the arrest *of this* man on a charge of obtaining money by false pretences on the 12th ultimo. He falsely represented that he was principal of the Bayer Co., Ltd., and obtained £21 from a man in Liverpool whom he appointed as his local agent. His description is as *follows*: about 36 years of age, about 5 feet 6 inches in height, slight build, fair hair, slight moustache, very prominent teeth, stoops slightly, walks badly, wears gold-rimmed eye-glasses; dresses in a frock coat and a silk hat. He is in the habit of calling at hospitals and upon medical men at their private addresses and, under the pretence of being connected with the firm mentioned, borrowing money which he does not pay back. He has already undergone a sentence of three years' penal servitude for obtaining money by false pretences. He has now left Liverpool but I hear that he is acting in a similar manner *in other towns*. I am very anxious to have him arrested, and my object in writing to you is to ask if you would kindly have a notice published in The Lancet requesting any medical man upon whom De Bayer may call to communicate with the nearest police station at *once, where the officer in* charge, by referring to case No. 36 in the *Police Gazette* of the 17th instant, can find a photograph of the accused *for identification*.

I am, Sirs, yours faithfully,

Francis Caldwell, Assistant Head Constable.

Central Police Office, Liverpool, W., May 21st, 1907.

THE DUTIES OF OPHTHALMIC OPTICIANS.

"The legitimate work of an ophthalmic optician is to make lenses for the *correction of ocular defects* according to any *formula* prescribed by a surgeon, and to set those lenses into a frame in such a manner as to insure the result intended by the surgeon." This statement merits the approbation of the medical profession. It is quoted from a pamphlet on "Comfort in Eyeglasses," issued by Messrs. Cary, Porter, Limited, Optical and Mathematical Instrument Makers. In these days when prescribing opticians are as numerous as the leaves in Vallombrosa the confession of faith would have been improved and its value intensified by the addition of the negative proposition that it is the duty of opticians to abstain from prescribing spectacles for their customers. In the covering letter which accompanied the pamphlet the firm add: "We do not attempt the prescribing of lenses, but devote our whole time and attention to the carrying out of oculists' prescriptions, and the careful fitting of spectacle and eyeglass frames." We regret that this sentence was not included in the text of the booklet, which is clearly intended for distribution amongst the general public.

The special feature to which Messrs. Cary draw attention is a patent machine for performing the dual operation of (1) céntring a lens, and (2) cutting it out to the desired shape and size. The instrument appears admirably adapted to insure accuracy in these important details. Illustrations are given of the deleterious effects of wrongly centred glasses. It is scarcely possible to lay too much stress upon the necessity for extreme accuracy in the adjustment of spectacle lenses. Though the surgeon's prescription may be correct all the benefits reasonably to be expected from the use of the glasses may be abolished by faulty workmanship; or still worse, the ocular defect may be aggravated.

It is our wish to support those honourable members of the trade who, recognising their own limitations, confine themselves to providing glasses with the greatest possible accuracy according to the surgeon's prescription. On the other hand, we have no desire to draw any invidious distinction between the individual firms of non-prescribing opticians. We shall therefore be pleased to publish a list of opticians who *guarantee* to work *only* from surgeons' prescriptions.

A NEGLECTED TEXT.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "M.D.," who quotes Judges ix. 12, 13, R.V., which in the A.V. is, "Then said the trees unto the vine, Come thou, and reign over us. And the vine said unto them, Should I leave my wine, *which cheereth God and man*, and go to be promoted over the trees?" evidently thinks he has settled the question of the use of wine or intoxicating liquor in moderation by this quotation from the parable of Jotham, but a close investigation of its origin will be seen to prove the contrary to what he imagines, and it is only fair to undeceive him.

It is obvious that because a remark is found in the Bible it is not therefore hall-marked as the thought of God Himself. Even the words of Satan, or the Devil, let alone ordinary men, are found in the Bible. See Job i. and Matthew iv. Who was Jotham? He was Gideon's youngest son, who escaped from being slain by Abimelech. That he was no prophet of the Lord is seen from his name in English. What does Jotham mean? In the Hebrew "Yah is Perfect," but what in English? Jotham can be split into two words "jot" and "ham." "Jot" is the smallest letter in the Greek, a dot or point, literally, a spot. "Ham" is the thigh of a hog salted and dried in smoke, and a hog, according to the Jewish law, was an unclean animal. "Ham" then is a concrete expression for what is "unclean." So Jot-ham means "spot that is unclean," and an unclean spot is the particular for *dirt*. This quotation then from the parable of Jotham, or personified *dirt*, one of the "spots" alluded to in II. Peter, ii., 13, only proves that it is physically, intellectually, morally, and spiritually of a like nature, or, in other words, an unclean and filthy perversion of the truth.

When we read Judges ix., 21, that after uttering this parable, "Jotham ran away, and fled, and went to Beer, and dwelt there ......" we are not surprised, for it is where everyone, figuratively speaking, goes who believes his words are true. They go to Beer because they take to beer as a drink, and to go to Beer is to go to *be-err* and not to be or to know truth or

SOBERNESS.

*** Our correspondent "M.D." made no allusion to the value of the text as an argument; he quoted it merely to wonder why no one had employed it as an argument, seeing how frequently other and less apt texts are employed Does "Soberness" in the circumstances think he is quite polite? Do our readers think "Soberness" is quite sane? Do the advocates of total prohibition of the sale of alcohol find him a valuable champion? We publish the letter in the faint hope that some disputants may learn the kind of thing which impedes honest argument about a question of supreme importance.—ED. L.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Westminster Gazette, Standard, Daily Chronicle, Edinburgh Dispatch, Morning Post, Daily News, Evening News, Yorkshire Observer, Optician, Glasgow News, Nottingham Evening News, Morning Advertiser, Glasgow Evening Times, Hudders-field Examiner, Nottingham Express, Aberdeen Daily Journal, Sunderland Echo, Manchester Dispatch, &c.*

Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (29th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (30th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.). Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

FRIDAY (31st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (1st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (27th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street Cavendish-square, W.).—8.30 P.M.: Annual Conversazione. 9 P.M.: Oration:—Dr. G. A. Gibson (Edinburgh): The Cause of the Heart Beat.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M.: Council Meeting. 8 P.M.: Casual Communication:—Mr. W. S. Handley: Lymphoid Degeneration of Salivary Glands. Paper:—Mr. J. H. Badcock: Interim Notes on Orthodontia. (The communication and paper will be illustrated by means of the epidiascope.)

TUESDAY (28th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M.: Sir William R. Gowers: A Case of Cervical Myelopathic Trichosis.—Major M. P. Holt, R.A.M.C.: Ligature of the Renal Vessels for the Cure of Persistent Urinary Renal Fistula, with One Successful Case. (With epidiascope demonstration.)

THURSDAY (30th).—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—5.30 P.M.: General Meeting. Election of Officers for the ensuing year. 6 P.M.: Address:—Dr. N. Moore: Air, Water, and Situation. 7.30 P.M.: Annual Dinner at the Trocadéro Restaurant, Piccadilly-circus, followed by an Entertainment.

FRIDAY (31st).—Epidemiological Society (11, Chandos-street, Cavendish-square, W.).—8.30 p.m.: Papers:—Prof. A. Holst (Christiana University): Studies concerning Ship Beri-beri.—Prof. Holst and Dr. T. Frolich (Christiana University): Polyneuritis in Poultry (Polyneuritis Gallinarum Eijkman) and Scurvy in Guinea-pigs.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (27th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Mr. G. Pernet: Clinique. (Skin.) 5.15 p.m.: Lecture:—Dr. J. M. H. MacLeod: Infantile Eczema, its Management and Treatment.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—9.30 a.m.: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Medical Out-patient (Dr. Whipham); Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 p.m.: Sir Dyce Duckworth: Medicine. 2.30 p.m.: Operations. 3.15 p.m.: Mr. W. Turner: Surgery. 4 p.m.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat. 4 p.m.: Special Lecture:—Dr. StClair Thomson: Surgical Anatomy of the Nose and its Accessory Cavities.

TUESDAY (28th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Dr. G. A. Sutherland: Clinique. (Medical.) 5.15 p.m.: Lecture:—Dr. F. J. McCann: The Treatment of Gonorrhœal Infection in the Female.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—10.30 a.m.: Medical Out-patient (Dr. Auld). 2.30 p.m.: Gynæcological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 p.m.: Dr. R. T. Hewlett: Medicine. 2.30 p.m.: Operations. 3.15 p.m.: Mr. Carless: Surgery. 4 p.m.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Skin.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 p.m.: Demonstration:—Dr. Atkinson: External Ear.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 p.m.: Clinical Lecture:—Dr. J. Taylor: Clinical Cases.

Royal Institution of Great Britain (Albemarle-street, W.).—3 p.m.: Prof. G. H. F. Nuttall: Malaria, Sleeping Sickness, Tick Fever, and Allied Diseases.

WEDNESDAY (29th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Mr. J. Cantlie: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. P. Stewart: The *Diagnosis of* Disseminated Sclerosis.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 p.m.: Dr. F. Taylor: Medicine. 2.30 p.m.: Operations. 3.30 p.m.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye.

University College (London) Medical Society (University College, Gower-street, W.C.).—8.30 p.m.: Paper:—Mr. W. Bateson: The Study of Heredity.

Asylum Workers' Association (11, Chandos-street, Cavendish-square, W.).—4 p.m.: Meeting.

Royal Sanitary Institute (Parkes Museum, Margaret-street, W.).—8 p.m.: Discussion on Suggested Amendments of the L.C.C. By-Laws as to Drainage (opened by Dr. L. C. Parkes, Mr. J. P. Barber, and Mr. I. Young).

THURSDAY (30th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. F. M. Sandwith: Cerebro spinal Fever.

North-East London Post-Graduate College (*Prince of Wales's* General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Special Demonstration on Medical Cases (Dr. Whiting).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. G. Rankin: Medicine. 3.15 p.m.: Sir W. Bennett: Surgery. 4 p.m.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat.

Charing Cross Hospital.—4 p.m.: Dr. Murray: Demonstration (Medical). (Post-Graduate Course.)

University of Birmingham, Faculty of Medicine (Medical Lecture Theatre).—4 p.m.: Post-Graduate Lecture:—Dr. O. J. Lewis: The Bacteriological Diagnosis of Diphtheria.

Royal Institute of Public Health (37, Russell-square, W.C.).—5 p.m.: Special Lecture:—Prof. R. T. Hewlett: The Problem of the Pure Milk Supply.

Royal Institution of Great Britain (Albemarle-street, W.).—3 p.m.: Lecture:—Prof. Sir James Dewar: Chemical Progress—Work of Berthelot, Mendeleeff, and Moissan.

FRIDAY (31st).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Dr. J. Horne: Clinique. (Throat.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 p.m.: Dr. R. Bradford: Medicine. 2.30 p.m.: Operations. 3.15 p.m.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Skin. 3.15 p.m.: Special Lecture:—Dr. R. Bradford: Hemiplegia.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 p.m.: Clinical Lecture:—Dr. J. Taylor: Sclerotic Diseases of Cord.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 p.m.: Demonstration: Dr. D. McKenzie: Thyroid and Cervical Region.

SATURDAY (25th).—London School of Clinical Medicine (Dreadnought Hospital, Greenwich.)—2.30 p.m.: Operations. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") *should* be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

Communications, Letters, &c., have been received from—

A.—Dr. J. Adam, West Malling; Dr. G. Emerson Arnold, Labasa, Fiji; A. R. G.

B.—Dr. U. N. Brahmachari, Calcutta; *Brain*, Lond., Editor of; *Birmingham Daily Post*, Manager of; Bradford Royal Infirmary, Secretary of; Berrow's Worcester Journal Co., Worcester, Manager of; Mr. C. Herbert Butcher, Birkenhead.

C.—Mr. David Clegg, Blackpool; *Convalescent Homes Association*, Lond., Secretary of; Central News, Lond., Manager of; Central London Throat and Ear Hospital, Secretary of; Cardiff Infirmary, Secretary of; Messrs. An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not *only affords* a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the *Office* not later than Wednesday, accompanied by a remittance.

Answers are now received at this *Office*, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; *copies only* should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable *to* the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and *other* Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France —J. ASTIER, 31, Rue Bapts, Asnières, Paris.

A Clinical Lecture

ON

PUNCTURED FRACTURES OF THE BASE OF THE SKULL.

Delivered at the Leeds General Infirmary,

By R. LAWFORD KNAGGS, M.C. Cantab.,

SURGEON TO THE INFIRMARY.

Gentlemen,—I wish to speak to you to-day about certain fractures of the skull which possess features of great interest. Fractures of the base are of three kinds: (*a*) fissures, the causation of which is still a ground of controversy; (*b*) comminuted fractures resulting from direct and great violence and which may be depressed; and (*c*) punctured fractures. The first variety is common, the second much less so, and the third is probably very infrequent, notwithstanding statements to the contrary, and when met with is usually unexpected. Though punctured fractures of the base have received but scant attention in surgical text-books they constitute a group which presents very marked peculiarities. These are of such importance that they justify the consideration of the group apart from similar injuries of the vertex upon which text-book accounts are usually based.

The rarity of these fractures is perhaps remarkable, for the configuration and structure of the base of the skull are such that penetrating wounds can easily be produced. But though the more vulnerable parts are sufficiently accessible to long, slender, and pointed objects, yet you will notice that they are most in danger when attacked from the front or the sides and there can be little doubt that the reason injuries of this nature are not more frequently met with is because the on-coming violence can be seen and, almost instinctively, avoided or minimised.

Anatomy.—If the base of the skull be examined it will be seen that the thin orbital plates and the brittle cribriform plate of the ethmoid can easily be pierced by a pointed instrument directed either through the orbit or the nose. It is possible, even without injury to the bone, for penetration of the middle fossa to occur through the anterior lacerated foramina along an orbital track, and a piece of tobacco pipe has been found in the cavernous sinus which had reached its destination in this way.[1] The floor of the middle fossa is much thicker than the orbital plates of the frontal bone but is still sufficiently thin to transmit light in most instances through the hollows that mark the points of pressure of the convolutions. The bone in this situation can easily be reached through the zygomatic fossa, the instrument entering through the cheek and perhaps passing between the jaws. A moderate amount of force would easily cause it to give way. The zygomatic arch forms quite a trap, and a pointed rod once pushed within it would, if the force were sufficient, almost certainly penetrate the skull. It might be directed against the base in the temporal fossa or the zygomatic fossa, or with a different inclination penetrate the anterior fossa after traversing the orbit. To the latter it could obtain access either by crashing through its outer bony wall or by hitting off the spheno-maxillary fissure. Next the buttress in the middle line formed by the body of the sphenoid is hollowed out into the sphenoidal sinuses and is really very thin. It would offer no serious obstacle to penetration, but it could only be assailed through the buccal or naso-pharyngeal cavities. The walls of the posterior fossa are, in the main, much stronger, but the thinner and often translucent parts upon which the lateral lobes of the cerebellum lie are protected by a mass of muscular insertions. This weak point has been penetrated from the mouth, the track passing between the transverse process of the atlas and the occiput. It would seem almost a necessity for such an injury to occur that the head should be placed in a condition of extreme extension upon the spine, and from the nature of the accident this was most likely to have been the case.

In this description the specially vulnerable portions of the base have been enumerated—the places where penetration can be and occasionally is produced by a comparatively slight amount of force. But no part of the base is exempt from the possibility of a penetrating fracture, provided it can be reached by a weapon sufficiently strong and under the influence of a force sufficiently great.

Three cases of punctured fracture of the base have come under my care in the infirmary and if I now describe them in some detail it is because each case has a special interest of its own and as a group they illustrate in a marked degree the peculiarities and the danger of this form of injury.

Case 1. *Penetrating wound of the orbit; fracture of the left orbital plate of the frontal bone; slate pencil imbedded and overlooked; septicæmia (?); death.*—A girl, aged four years, was returning from school on Feb. 19th, 1904, with a slate pencil in her hand when she fell and wounded herself with it. She walked home and was taken to see Mr. H. Bailey of Horsforth the same afternoon, who gave chloroform and felt a portion of the pencil deeply placed in the orbit. He then directed the friends to take the child to the infirmary at once, and having received a very urgent call to another case at that moment he sent a verbal message by the mother. The child reached the infirmary about 9 P.M. and was carefully examined by a resident officer of proved capacity. The pencil was not detected and the patient was allowed to go home. It is needless to add that the message, as it was delivered, tended to mislead rather than to help. On the 20th the child vomited several times and towards evening became delirious. In the night Mr. Bailey found the temperature 104° F. On the next morning she was admitted. The temperature was then 104·6°, the pulse was 160, and the respirations were 52. She wandered in her talk and did not take in anything that was said to her. She was continually throwing her limbs about, but there were no convulsions, no paralysis, no rigidity of the limbs, and no retraction of the head and neck. The lids of the left eye were infiltrated with blood and much swollen and there was chemosis. With difficulty it was seen that the eye was depressed and it was subsequently ascertained that the child had had double vision after the accident. There was a small wound *above* the orbital margin and under an anæsthetic it was thought one end of the pencil could be felt through the swollen and tense upper lid. An incision through the lid enabled the pencil to be grasped with forceps, but it was so firmly fixed in the bone that it required a good pull to draw it out. A flap was next turned down from the forehead and the anterior fossa explored through a trephine aperture above the orbital ridge. The position of the supposed fracture was too far back to be exposed, but a searcher, passed over the part where it would be, detected no fragments of bone. It was also passed between the periosteum and the roof of the orbit without gaining further information. Finally, the flap was replaced and a drainage-tube passed along the track of the slate pencil through the incision made for its extraction. The pencil, which was about one and a half inches long, had entered by the wound *above* the eyebrow. The operation had no effect upon the symptoms and death took place at 6 P.M. on Feb. 21st.

At the necropsy no adequate cause of death was found. There was a small fracture—almost a fissure—of the left orbital plate of the frontal bone. It was half an inch long and was a quarter of an inch in front of the foramen lacerum anticum. Its edges were very slightly raised towards the brain. The dura mater had not been penetrated and there was a little blood adherent to it over the seat of the fracture. There was no meningitis. (Specimen A 12c, University of Leeds Pathological Museum.)

Case 2. *Penetrating wound of the middle fossa; transfixion of brain.*—A boy, aged 14 years, was running along a workshop with a long iron rod in his hand when he tripped and fell and the rod penetrated his cheek. He pulled it out himself. This happened on Dec. 12th, 1901. The wound was dressed by a medical man who referred him to the infirmary for subsequent treatment. He seemed dazed after the accident. On the next day he presented himself at the casualty department with a septic inflamed wound in the *right* cheek and whilst waiting to be attended to he seemed unable to keep awake. This attracted the attention of the casualty officer and the boy was admitted. Beyond a slight elevation of temperature and marked drowsiness there was an entire absence of symptoms. When roused he would sit up and answer intelligently but in an apathetic way any questions addressed to him and as soon as they were discontinued he would drop down in bed and fall asleep at once. He would feed himself but would go to sleep between the mouthfuls. He would reach his urinal but would fall asleep with it in bed and probably upset it.

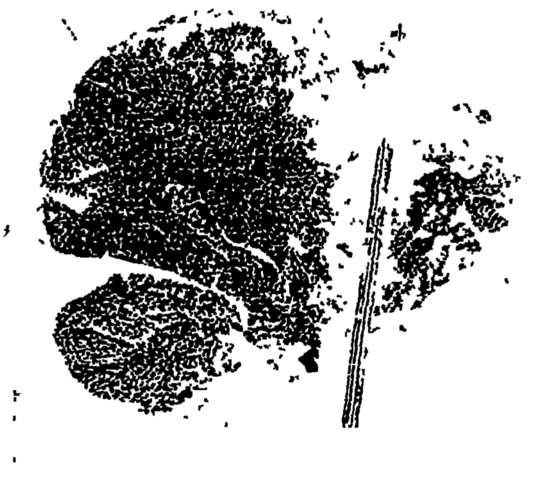
---

e Eye, second edition, p. 17.

On the 16th the house surgeon asked permission to send him home, as beds were needed. On the 17th he was called to the lad at 9 A.M. because he had had a fit. On his arrival the convulsion had passed off but the patient was unconscious and evidently sinking. The convulsions recurred before death. The final scene only occupied half an hour.

Subsequently it was found that the rod, after penetrating the cheek, had passed inside the zygomatic arch, breaking back, but not detaching, a small fragment of the coronoid process of the mandible. It had then passed through the great wing of the sphenoid one-third of an inch external to the foramen rotundum. The aperture would admit the first phalanx of the little finger and thin plates of bone had been upturned towards the brain almost of the same size as the aperture. These plates of bone are well shown in the macerated specimen (A 12b, University of Leeds Pathological Museum).

The track in the brain began near the apex of the right temporo-sphenoidal lobe and, with an inclination inwards, passed through the posterior part of the frontal lobe and ended on the convexity close to the longitudinal fissure and about two and a half inches behind the frontal pole. The pia arachnoid was lacerated at the point of emergence but the dura mater was not perforated. The lenticular nucleus abutted on the posterior edge of the track and surrounding the latter for half an inch or more the brain tissue was infiltrated with blood and evidently much altered. The lateral ventricle does not appear to have been opened. (Specimen No. 77.)



Specimen No 77, Pathological Museum of the Medical School of the Leeds University From a boy whose brain was transfixed by an iron rod which entered through the cheek He was not brought for treatment for several days and death occurred unexpectedly about a week later.

CASE 3. *Punctured wound of the anterior fossa; operation; cerebral abscess (?); second operation; recovery.*—On June 11th, 1904, a boy, aged 12 months, was left by his mother playing with a long bone crochet hook. On her return she found the child with the handle end of the hook protruding from the inner surface of the upper lip. On admission to the infirmary shortly after Mr. Coupland, the resident medical officer, extracted it. First marking with his finger the point at which it emerged from the lip he found that the end was engaged in bone and caught. Gradually turning it he disengaged the hooked end and withdrew it easily. The part that had penetrated measured three inches and from its direction it must have pierced the orbital plate of the frontal bone Upon these facts I decided to explore. Through an incision along the supra-orbital ridge the roof of the orbit was examined and a fracture detected to the outer side of the middle line and half an inch from the ridge. A frontal flap was then turned down and through a large trephine opening above the ridge the dura mater was lifted up from the floor of the anterior fossa. A small round hole about six millimetres in diameter was seen in the bone and there was a corresponding aperture in the dura mater. A sharp fragment of bone was felt within the dura mater and easily extracted through the opening. It was insufficient to fill the hole in the bone, but no other fragment could be found. The dural aperture was inaccessible to suture. The flap was replaced and a light gauze packing left in in case the crochet hook had infected the parts. At first the progress was satisfactory and the wound slowly healed. A small abscess formed near the inner canthus in the second week and cleared up and there were one or two isolated acts of vomiting, but at the beginning of July the child became gradually torpid and dull and at last unconscious, though still able to swallow. On July 11th optic neuritis was developing in the left disc. On this date a further operation was performed. The trephine opening was exposed and the bulging dura mater slit open. The brain immediately began to protrude and presented a pearly white pulpy appearance. It pulsated freely, but was not at all like healthy brain tissue. The trephine opening was enlarged and the brain protruded until a hernia as big as a plum had formed. This was explored with a glass trocar which was pushed towards the part injured by the crochet hook, but nothing escaped. The flap was replaced over the hernia and held in position by two or three sutures. After this operation the child began to improve and to take notice of things and to behave like an ordinary baby. There was no more vomiting but the hernia increased. Some œdema developed in the left temporal region and the ends of the flap incision were separated by forceps and some sero-pus escaped. On the 14th a considerable amount of rather offensive pus escaped and next morning the hernia underneath the flap had very markedly subsided. From this date all went well and by August 7th there was no sign of any protrusion of brain through the opening in the skull and the child was convalescent. He was discharged on Sept 9th.

During convalescence and when the bandages were removed an internal strabismus of the left eye was noticed. It disappeared after some months and very possibly may have been connected with injury to the external rectus muscle as the crochet hook pushed aside the eyeball in its passage across the orbit. The child is now perfectly well and presents no sign of any trouble resulting from the cerebral mischief.

Cases of this nature must always make a great impression upon those under whose care they fall, therefore it is astonishing to find how seldom they seem to be recorded Plenty of cases could be brought forward, more particularly from the older writers such as Morgagni, Bonetus, and others, and it may be that these wounds, not a few of which were caused by swords, were more common in the Middle Ages when duels were of almost daily occurrence. Mackenzie, in a work on "Diseases of the Eye" (1835), gives details of 11 cases, all, however, occurring through the orbit Let me now give you a short account of eight cases of later date They are all well worth listening to and will help us to take a wider view of the subject and pave the way for its general consideration. Bullet wounds of the base I have purposely excluded, for they constitute quite a different class of injury, also with definite and distinctive features. They are not uncommon, and Dr. John A. Liddell has given an account of 135 cases which all recovered.[2]

CASE 4 (recorded by Dr. Cornelius Williams).—A butcher, aged 48 years, whilst hanging meat, fell against some iron hooks fixed to a beam and remained suspended for several minutes upon one, which transfixed his right cheek. He walked to a hospital and had the wound attended to at once This happened on Nov. 16th On the 19th he applied at the Mount Sinai Hospital on account of a blood-shot eye and chemosis. The cheek wound was suppurating. The real nature of the injury was not at this time diagnosed. Two days later, at his second visit, cerebral symptoms had appeared (pyrexia, stupidity, and pain in the head). The same night the site of the fracture in the orbital plate (1¼ inches from the upper margin of the orbit and a little to the outer side) was exposed by dislocating the orbital contents downwards and inwards On reaching the point of fracture a tablespoonful of very fœtid red-coloured pus escaped with a quantity of gas Temporary relief followed, but death took place on Nov. 24th.

Post mortem it was found that the hook had entered the cheek and passed behind the zygomatic process of the malar bone through the spheno-maxillary fissure, fracturing the bones on either side, and through the roof of the orbit, producing a comminuted punctured fracture, lacerating the dura mater, and forcing several plates of the thin bone into the substance of the brain. There was a cone-shaped abscess in the brain with its apex upward which was surrounded by a zone of diffuse cerebritis. There was also intense congestion of the entire brain and pus was observed in the pia mater of the vertex.[3]

---

[2] American Journal of the Medical Sciences, vol. lxxxi., p. 335, 1881.

CASE 5 (Specimen No. 851, Museum of the Royal College of Surgeons of England).—"The lower portion of the frontal bone and the adjoining portions of the nasal bones. A puncture passes through the orbital plate entering by the side of the right internal angular process and opening into the skull about half an inch to the right of the crista galli. The specimen was taken from a butcher's boy, aged 13 years, who inflicted the injury on himself whilst cutting a skewer, probably by thrusting the skewer into the orbit. Death took place four days after the accident, apparently owing to fresh hæmorrhage effused into the skull from a fall after the external wound had closed. (See *Edinburgh Monthly Journal of Medical Science*, 1842.) Presented by Dr. Peacock, 1876."

CASE 6. *Punctured fracture of the orbital plate; meningitis.*—A man, aged 40 years, fell from a scaffold and was admitted into the infirmary under the care of Mr. E. Ward. He could speak when admitted. He had an attack which resembled delirium tremens and died on the third day. Post mortem a small wound *above* the right eyebrow was found to lead into the cranial cavity. The orbital roof was punctured and the bone was somewhat comminuted. The under surface of the right frontal lobe was lacerated over the fracture and there was meningitis of the base extending into the spinal canal. There were other visceral injuries but the cause of death was the meningitis.

CASE 7. *Punctured fracture of the roof of the orbit; meningitis.*—This case is taken from a sensational paragraph in the *Yorkshire Evening Post*, entitled "A Bit of Wood in his Skull." A boy, aged three years, on Jan. 23rd was running about the house and playing as usual and carrying a piece of a clothes-peg in his hand. He fell and then blood was noticed coming from his eye. At the hospital the wound was attended to by the assistant house surgeon. At the inquest the medical evidence went to show that though a careful examination had been made the presence of a foreign body was not detected till Jan. 31st, when a piece of wood one and a half inches long and firmly imbedded in the skull was removed. The post-mortem examination showed that death was due to septic meningitis caused by the foreign body puncturing the roof of the orbit and the membranes of the brain. The observations of the coroner, thought worthy of reproduction, were the following: "He thought it was a most extraordinary thing that a piece of wood should get into a child's eye and should be undiscoverable for so many days, notwithstanding the numerous medical examinations that were made. They did not want to reflect improperly upon anyone, but it certainly gave the impression that there was not a proper examination of the eye made by the doctor who first saw it." The jury added a rider to their verdict to this effect: "That *they thought* [the italics are my own] that had the hospital doctor inquired how the cut occurred he might have considered it necessary to make a search for the piece of wood."

CASE 8. *Penetrating fracture of the base, passage of the weapon through the brain and the vault of the skull; recovery.*—This is the celebrated case of Phineas P. Gage, aged 25 years. Whilst engaged in blasting operations a smooth iron rod 3 feet 7 inches long and 1¼ inches in diameter, having a tapering point and weighing 13¼ pounds, passed completely through his head and high into the air. The rod passed through a wound in the cheek, external to the ascending ramus of the lower jaw, beneath the zygoma, entered the skull in the temporal fossa, and emerged where the two parietal bones join the frontal bone. There were much hæmorrhage and escape of brain matter. The patient spoke in a few minutes after the accident and could walk and give an account of how the accident happened very shortly after. He had a long illness[4] but nine or ten weeks later he was walking about the house and appeared likely to recover if he could be controlled. Dr. H. J. Bigelow, whose account I have followed, states: "from this extraordinary lesion the patient has quite recovered in his faculties of body and mind, with the loss only of the injured eye" (viz., the left, which was protruded at the time of the accident).[5]

CASE 9. *Penetration of the middle fossa by a railing spike; meningitis* (Mr. John Cowper's case).—A house painter, aged 25 years, fell with a ladder and struck his head sideways upon some railings. The terminal portion of a spike (more than two inches long) broke off and remained fixed in the skull. It entered under the apex of the mastoid process, traversed the internal ear, drove portions of the petrous bone through the dura mater, formed a considerable aperture in the bony floor of the middle fossa, and wounded deeply the posterior part of the right middle lobe. The spike was extracted but the patient died from meningitis nine days later. Except in the immediate vicinity of the wound the brain was normal.[6]

CASE 10. *Punctured fracture of the base; meningitis.*—Specimen 1086^{53}, Guy's Hospital Museum, is a portion of a frontal bone which has been pierced by a piece of wood. A man, aged 60 years, fell whilst running down hill and struck the right side of his head against a tree. A piece of wood was found to have entered the orbit from the outer side and caused destruction of the eye. He died two weeks later after cerebral symptoms had supervened. Post mortem a punctured fracture of the frontal bone was found close to the external angular process. Between the dura mater and the bone were found purulent lymph and small chips of wood (one round and pointed) and pieces of in-driven bone. On lifting up the dura mater a small hole was found in it opposite the fracture and the brain itself showed slight marks of injury and was softened, dark, and covered with inflammatory lymph at this part. (Constructed from the museum catalogue and the report of the post-mortem examination.)

CASE 11. *Punctured fracture of the posterior fossa through the mouth; injury to the cerebellum; meningitis* (Dr. W. Thyne's case).—A boy, aged five years, was standing on a snow heap holding a piece of gas piping which contained a steel umbrella rib projecting some inches. The steel rib was inserted into his mouth to imitate the bagpipes. He fell and caused the umbrella rib to penetrate the posterior wall of the pharynx. It was extracted by a bystander. There was slight oozing of blood and he appeared to recover. He was admitted to hospital the next evening with cerebral symptoms. There were convulsive movements of the right side of the face, conjugate deviation of the eyes to the left, unconsciousness, persistent vomiting, and a temperature varying from 104° to 107° F. Death took place 24 hours later. At the necropsy there was suppurative meningitis of the base, also laceration of the right cerebellar hemisphere adjacent to a fracture in the right posterior fossa external to the posterior condyloid foramen. A probe was easily passed through the puncture into the mouth. The umbrella rib had passed between the occiput and the transverse process of the atlas.

From a consideration of these cases it will be seen that the salient features of punctured fractures of the base are: (1) the frequency with which they are overlooked; (2) the not uncommon retention of a foreign body the presence of which is quite unsuspected; (3) the almost universal tendency to septic complications if the more immediate danger of death from intracranial hæmorrhage and cerebral injury is escaped; and (4) their fatal character.

1. *The frequency with which the true nature of these cases is overlooked.*—There is no fact that stands out so prominently as this. Hulke, writing in Holmes's "System of Surgery," says: "Two or three days may pass over during which the patient goes about as usual, then brain symptoms make their appearance, sometimes suddenly, and the patient dies in the course of a few hours or days and the true nature of the case is revealed only by the post-mortem examination." Recorded cases fully bear out this statement, and it may be regarded *as the rule*, unless the gravity of the external injury is too obvious to be overlooked, as in the case of Gage, or unless pronounced symptoms suggestive of intracranial hæmorrhage or of a gross lesion of the brain follow quickly on the injury.

In my first case it was particularly unfortunate that the value of Mr. Bailey's early recognition of the facts was nullified by the failure to confirm them at the infirmary. The occurrence was taken very much to heart and no doubt proved a valuable object lesson to those who were in residence at the time, and it is possible that its influence was reflected in the creditable observations which enabled the third case to be saved. The remarks of the coroner and the rider of the jury in Case 7 would at first sight appear perfectly fair and natural even to professional readers, but had the coroner's experience of these cases been more extensive it is certain that he would have summed up very differently.

---

[3] Medical Record, 1879, vol. xvi., p. 56.

[4] The illness was no doubt due to encephalitis, for at the end of ten days he lay in a semi-comatose condition for another ten days and hernia cerebri formed.

[6] London Hospital Clinical Lectures and Reports, 1865, vol. ii., p. 245; also Hutchinson's Illustrations of Clinical Surgery.

Now it is evident that there must be some circumstances, apart from professional carelessness or incompetency, to explain this frequent non-recognition of penetrating fractures of the base of the skull. Let us briefly consider four which are of much interest.

In the first place, there are the paths by which an offending instrument may reach the base. (*a*) The most usual is *through or across the orbit*. In six of the 11 cases I have described the weapon took this course. The orbit is not necessarily entered from the front, but may be crossed from below upwards or reached from inside the zygomatic arch, and the position of the skin wound may in some cases be such that it will fail to arouse suspicion. (*b*) A much less frequent one is through the mouth and pharynx or through the nose. The latter, however, must be very rarely taken, for I have not come across a single instance except as part of an orbital wound. (*c*) Another important and not uncommon route passes *inside the zygomatic arch*. The external wound is usually in the cheek and the lower jaw may be damaged. (*d*) Lastly, the convex portion of the base—viz., the posterior segment of the skull—may be wounded directly. It is in the cases that fall into the first three groups, or, in other words, where penetration takes place through the cavities and fossæ which lie anterior to the foramen magnum, that failure to recognise the nature of the injury is usual. And it is to one or other of these groups that the large majority of cases of punctured fracture of the base belong.

In the second place, appearances are often misleading, and it must be admitted that even in the simplest cases detection is far from easy if symptoms of intracranial injury are not present. It is obvious, after what has just been stated about the different ways of approach to the base, that *the superficial wound, which is usually trivial, must often be at a considerable distance from the opening in the skull, and it is in this fact that the great difficulty of making a correct diagnosis lies*. The wound on the surface and the hole in the bone are connected by a track which is apt to be bent at an angle in consequence of the gliding of moveable skin or to be more or less circuitous owing to the return to their original positions of structures pushed aside by the penetrating object. In other cases the track may lie in the soft, almost diffluent, fatty orbital tissue. But if the aperture of entrance should chance to be in the pharynx or the nose it may escape observation altogether even after careful examination.

A third cause of uncertainty or difficulty in diagnosis may be found in the lightning-like rapidity with which the wound may be inflicted and the weapon withdrawn. This difficulty is particularly apt to be present in the cases of wounds inflicted in fencing. But it is worth noting that the withdrawal is sometimes made in a moment of excitement by a bystander or even by the patient himself, and in either case accurate observations are not likely to be forthcoming.

Lastly, strange as it may seem, the wounds in a fair proportion of these cases are regarded by the patients as too trivial to worry about, so they are apt not to seek advice until the onset of serious symptoms makes a professional error unlikely.

These remarks apply more particularly to cases where the base is penetrated in front of the foramen magnum or reached from the front through one or other of the various cavities and fossæ. Punctured fractures of the base reached directly from the exterior in the posterior segment of the skull resemble in the main similar fractures of the vertex, except that the opening in the bone lies at a deeper level owing to the mass of muscles inserted into the occipital and mastoid bones. With ordinary care they are not likely to be overlooked and in most cases will probably be due to considerable violence. (Case 9.)

2. *Unsuspected retention of the foreign body.*—This, as you will have noticed, occurred in two instances in the 11 cases I have narrated (Nos. 1 and 7). They do not stand alone. Mr. Hulke records another in which, after a portion of slate pencil impacted in the frontal bone had been removed, another portion an inch long was found post mortem in an abscess in the right frontal lobe.[7] This is on all fours with Case 10, in which chips of wood were found within the skull after death, having escaped detection at an operation. And I have already referred to a case in which a portion of tobacco pipe was removed from the orbit, after a tardy onset of symptoms caused the patient to seek advice. The patient died and a piece of the pipe an inch long was found in the cavernous sinus, having reached that spot through the foramen lacerum anticum.[8]

In all these cases, as might be expected, the objects that caused the injuries were so brittle that they would snap under a slight degree of force. Moreover, they were long and slender. Had the retained portion not been slender it would seem impossible for it to have escaped attention. But a foreign body left behind is not always due to a fracture of a brittle weapon. A brass ferule has been found near the sella turcica in a man who died a few days after being struck on the side of the nose in a fencing bout with walking-sticks.[9] Now it is in these cases in which a fracture is produced *viâ* the orbit that a portion of the object that causes it is so apt to be left behind and overlooked. It is easy to understand how a foreign body such as a slate pencil may find a hiding place in that deepest cavity, but it is astonishing how large an object can lie in it and escape recognition. Ormonde[10] refers to a case recorded by Mr. C. Higgens, in which the blade of a penknife had been imbedded in the orbit and frontal sinus for 46 years without the patient having the slightest suspicion of its presence, and Treves[11] mentions an instance of a piece of an iron hat-peg, three inches long, being imbedded for several days without the patient being aware of it.

The difficulty of recognising the presence of a foreign body in the orbit would not be so great if the contents of that cavity were in their normal condition, but œdema, and possibly hæmorrhage into the loose cellular tissue, takes place so quickly after the injury that in a very short time a state of affairs is produced in which a deeply seated firm substance may only be capable of detection when the patient is anæsthetised. Great help would be given in these cases if a clear history of the facts could be obtained, but often this is not forthcoming or may fail to be rightly understood. One practical point, however, I would impress upon you: insist upon having the offending instrument brought for your inspection. You can then satisfy yourself as to the possible extent of penetration and recognise if there is any sign of a recent breakage.

3. *The tendency to septic complications if the more immediate danger of death from intracranial hæmorrhage and cerebral injury is escaped.*—I have not come across a single instance in which some complication of a very serious character was not present. The symptoms dependent upon the complications may occur immediately or may be deferred for several days. The former are usually the consequence of hæmorrhage or of laceration of the brain, the latter of septic inflammation. And the first, if not fatal, merge into the second. Now with reference to the question of hæmorrhage, let me remind you that it is at the base of the skull that the majority of the venous sinuses are situated, and at the central portion of the middle fossa the cavernous, the circular, and the petrosal sinuses are crowded into a small area. The large arteries and their chief branches are also snugly arranged in this neighbourhood. It is hardly necessary to enumerate the carotids and middle meningeal arteries outside the dura mater and within it the circle of Willis, with the anterior and middle cerebral arteries and the basilar and posterior cerebrals, for you to picture to yourselves how likely some of these vessels are to be injured when penetration takes place towards the centre of the middle fossa. And not only is this mid-region of the middle fossa packed with blood-vessels, but resting upon it and in close relation to it are some of the most important parts of the brain. It may be regarded, therefore, as *the most dangerous region* at the base in which a penetrating fracture can occur. Consequently it is distinctly unfortunate that owing to the shape of the orbits and the inward inclination of their outer walls a pointed weapon entering horizontally must almost inevitably be directed into this part of the skull.

Let me give you one instance in illustration. A man dropped down dead in a scuffle after receiving a penetrating wound of the orbit with the point of an umbrella. Considerable bleeding had taken place from the nose and mouth and it was subsequently found that much blood was effused into the membranes of the brain and that the brain and dura mater were lacerated. Penetration appears to have occurred close to the body of the sphenoid.[12]

[11] Surgical Anatomy: Lawson's case.

[12] Mackenzie: *Diseases of the Eye*, p. 9, Case 16.

Then there is a point of very considerable interest in connexion with the wounds of the brain in these cases. Penetration for long distances is not uncommon. The brain on the table from Case 2 shows a track from base to vertex. In a wound of the left orbit related by Ruysch the stick had penetrated "to a considerable depth" into the brain. In another (Peter Borel) a sword entering the left orbit had penetrated to the cerebellum. In a third (Diemerbroeck) a sword thrust in the inner canthus of the eye traversed the corresponding lateral ventricle and almost passed through the skull at the upper angle of the lambdoidal suture. In still another an umbrella point injuring branches of the middle cerebral artery pierced the left crus, passed "into the right lateral ventricle, and must have penetrated the central parts of the brain to the depth of at least two inches."

But I have said enough. Let me pass to the later or septic *complications*. These are meningitis, encephalitis, and cerebral abscess, and if the "immediate" conditions, which I have just discussed, should be absent, or should fail to produce a rapidly fatal issue, one or more of them will inevitably supervene. There is no difficulty in understanding this. When the dura mater or the brain is penetrated septic organisms are carried directly to the intracranial contents, whether the wound is at the base or at the vertex. *On the vault of the skull the injury is evident*, it is surgically treated at once, and there is a reasonable probability that it is rendered aseptic. At the base, on the other hand, as we have seen, the real character of the injury is apt to be overlooked entirely and occasionally a septic foreign body may be allowed to remain imbedded.

In none of these cases is any attempt made to secure asepsis when it might avail. In others, though the nature of the injury may be appreciated, the position of the cranial wound may be such that surgical interference is practically impossible. And in still others the track to the brain and its meninges starts from a cavity swarming with bacteria. The very large majority of the recorded cases—in fact, nearly all —fall into one or other of these groups. But Case 3 shows that surgery can be useful and that even though a grave septic complication results it may in some cases be possible to guide it to a satisfactory issue.

Active surgery is not essential to success, as the remarkable recovery of Gage teaches us. And another very interesting case helps to enforce a similar lesson. Selwyn has recorded it. A cheese knife entered the right orbit of a boy, aged four years, for three and a half inches and was only withdrawn by considerable force. Brain matter protruded on withdrawal and more escaped on the eighth day, whilst vision was entirely lost in that eye. Recovery took place under simple treatment[13] and the lesson is—the value of a free opening for the swollen brain to protrude through and for inflammatory discharge to drain from.

4. *Their fatal character.*—This, the fourth salient feature of these fractures, does not call for much comment now, for almost every point that bears upon it has already been considered. From the historical point of view you may be interested to know that the injury in Gage's case was so remarkable and recovery considered so wonderful that Bigelowe thought it desirable—possibly for the benefit of his transatlantic cousins—to support his account of the case by the affidavits of eye-witnesses and others who could testify to its reality. The contrast between Gage's case and Selwyn's case of recovery on the one hand and the numerous fatal cases in which the injury was apparently so trivial as to be disregarded on the other cannot fail to impress you.

The number of cases of recovery are very few. I have given prominence to all I could find records of and as you see they are not numerous (Gage, Selwyn's, and Case 3). Morgagni refers to others by Borelli, Fantonus, Elias Camerarius, and Nobelius,[14] but I am unable to give you any particulars about them.

Lastly, a fracture which is very different in its causation from those which have furnished the subject matter of this lecture, but which belongs to the same type, is one of which two cases are mentioned by Mr. Hulke in Holmes's "System of Surgery." In this fracture the condyle of the lower jaw is driven forcibly through its fossa and projects into the skull. In one (Chassaignac's) the man died some months later with an abscess in the middle lobe of the brain against which the condyle was pressing. The other is a specimen in St. George's Hospital Museum.

A Lecture

ON

SURGICAL AFTER-TREATMENT.

Delivered before the Lancaster Medical Book Club

BY B. C. STEVENS, M.D., M.S. DURH., F.R.C.S. EDIN.

GENTLEMEN,—There is no doubt that this subject is an all important one, both to the operating surgeon and to the general practitioner. A brilliant operation may have been performed but the after-treatment left in unskilful or inexperienced hands and an otherwise successful case turns out a miserable failure. Success in surgery, as well as in all other callings, depends on attention to detail. So a sin of aseptic omission or of septic commission may spoil an otherwise brilliant operative result. One cannot dogmatise in a discussion on after-treatment because, after all, it resolves itself into the ultimate and best results obtained in cases under the personal care of the individual surgeon. After-treatment is essentially a subject in which success depends a great deal on the *surgeon's ego, tact, common* sense, and *consideration*; his insight into his patient's character, nervous system, powers of endurance, and means of comfort; and, above all, on the surgeon's appreciation of human nature and weakness.

To come to the point: Take the case of a patient who has just undergone an abdominal operation. The patient should be kept flat on his back for two hours and then propped up a little. The dorsal position so often adopted is not natural and is often uncomfortable. Consider the badly covered bony parts and the risk of "acute decubitus." This position is said to be the cause of cystitis in women. Children should not be strapped down; bodily comfort means nervous and mental rest and quicker convalescence. The right lateral recumbent position is best for natural drainage, as in stomach and appendix cases, while the semi-recumbent dorsal position is good for artificial drainage.

The thirst should be quenched by frequently rinsing the mouth with hot or cold water, or thirst may be forestalled by a large saline enema or by leaving a considerable quantity of saline solution in the peritoneal cavity. After the anæsthetic vomiting is over give a liberal allowance of fluid by the mouth, including weak tea if desired.

Much of the pain present is due to spasm of the abdominal muscles; this can be relieved by relaxing the muscles by propping up the shoulders and flexing the knees over a pillow. Try to avoid giving morphine—rather give atropine, aspirin, or sulphonal. Remember that opium masks the symptoms of intestinal obstruction or peritonitis and may deceive both surgeon and patient in gauging the urgency of the case.

The diet for the first 48 hours is important. In most cases there is no need to rely on rectal feeding, though this is a useful adjunct, especially as a means of introducing fluid into the thirsty capillary system. A good nutrient enema is easily made by giving one fluid ounce of Carnrick's liquid peptonoids or panopepton in four fluid ounces of water. Milk should be more and more avoided both before and after operations; it is often not digested but forms a tough *mass* in the stomach and leaves a bulky residue in the intestines, causing a foul odour of breath and fæces by its lactic acid fermentation. Beef-tea also is an over-vaunted diet. The best beef-tea contains only 3½ per cent. proteins. The best foods after an operation of any severity are raisin-tea (for the glucose), albumin water (for the protein), and plasmon powder in hot water or in weak tea and broth. Ordinary fluid nourishment may be given as well, also fruit jellies and meat jellies and peptonised milk chocolate. If rectal feeding has to be persevered with the rectum must be washed out daily with warm boric lotion. Enemata often upset the patient by causing vomiting, rashes, and rises in temperature. If rectal *feeding* is going on regularly it is difficult to regulate the flatus tube which, if necessary, should be introduced half an hour before the nutrient. In some cases a fluid dietary sets up flatulence; if so, give semi-solid food such as Benger's, bread and milk, arrowroot, or Allenburys milk and cereal diet. If nutrients are not given leave a flatus tube in the rectum for from 24 to 48 hours after an abdominal or a perineal operation; it is a great comfort in preventing flatulence, meteorism, and perhaps peritonitis.

In passing a catheter after operations always wait 24 hours (as there is not much urine secreted at first) and then use, if possible, a boiled one of soft rubber and lubricated with sterilised olive oil. In nearly all cases the bowels should be opened on the third day preferably by a simple enema preceded if desirable by an olive-oil injection especially in rectal cases. Five grains of calomel may be given on the evening of the second day as a rule. Enemata act without much peristalsis, which is not always an unmixed blessing, as peristalsis is beneficial, especially after appendix operations and abdominal uterine operations. A little rise in temperature the first two days is usually reactionary and means nothing serious; the more pronounced the shock of the operation the longer the reactionary temperature takes to appear and disappear. Usually if the pulse keeps below 100 the patient is doing well and there is no danger of peritonitis.

Where drainage by gauze wick, split rubber tubing and gauze together, or glass or rubber tubing has been instituted remove the gauze in 48 hours and shorten the tube a little. If necessary re-introduce fresh gauze (boiled) either by the side of, or inside, the tube. The advantage of the split rubber tube is the facility with which gauze can be placed inside it either *in situ* or *ex loco*. Glass or rubber tubes should not communicate directly with the outer air but must be covered by some antiseptic gauze. All drainage appliances must be adequately secured outside the body. Where drainage is only established for a short time a skin suture is often left ready to be tightened up when the tube is removed. In every case where the dressing is "through" if it is not changed throughout it must be re-packed with sterilised wool and re-bandaged with a sterilised bandage. Bottles or jars into which fluids drain from wounds through tubes should either be air-proof or contain some antiseptic solution.

Three weeks in bed is the usual period of rest after a laparotomy, but in some cases of hernia sutured with strong material and in some appendicectomies done by the "gridiron" operation patients may get up in from 10 to 14 days. Sutures should not be removed early unless causing irritation, and in all cases must be removed with sterilised instruments. With the forceps draw up one side of the suture so as to bring to light a buried portion of it and snip this through; by this means in withdrawing the suture you run less risk of infecting the deeper tissues. If there is a "stitch abscess" to deal with it is better simply to cut the suture and leave it until the wound has been purified in case of infecting deeper tissues. Strapping is most useful after a laparotomy and is usually applied over the gauze and wool dressing; over the strapping are usually placed more sterilised wool and a many-tailed bandage. In dressing the case afterwards all that is necessary is to cut the strapping obliquely and then to fasten it again with safety-pins; the extra support which strapping affords is of value in securing primary and firm union. When the patient is allowed up a well-fitting belt with a pneumatic pad to fit the scar is usually worn for six months.

Surgical shock has, if possible, to be prevented by judicious ante-operative treatment, such as rest and warmth in bed before the operation, a warm operating table and room, and the avoidance of noise, confusion, and display. The patient should be covered, so far as is convenient for the operator, with a Gamgee suit. The patient's system must not be drained of fluid by starvation and purgation. He may have a preliminary hypodermic injection of digitaline or strychnine or an enema of black coffee or of saline solution and brandy. These stimu- lants are useful in averting shock but practically useless in combating it. During the operation the anæsthetist is largely responsible in averting shock by the method he employs to save cardiac strain and pulmonary engorgement and pain. The surgeon is responsible by reason of his dexterity and control of hæmorrhage. In quite recent times the employ- ment of cold mackintoshes and wet carbolic towels has added to the risk of surgical shock.

The main factor in shock is the fall in general blood pressure. The tachycardia is not so much due to a failing heart muscle as to its having not enough blood to work on. Shock is due to exhaustion and breakdown of the vaso-motor centre; the blood collects into the splanchnic area and the patient bleeds into his own veins, so to speak. Neurotic shock is seen in patients whose nervous centres are exhausted by pain, malnutrition, and disappointment; they make up their minds to die and often succeed. Secondary shock is seen in debilitated and emaciated people; they have dry fauces, pinched features, sunken eyeballs, cold and blue extremities, a small quick pulse, and scanty urine. There are congestion of the gastric mucous membrane and coffee-ground vomiting; this is attributed by some to sepsis, but the real cause is the draining away of fluid from the tissues. The treatment of neurotic shock is by morphine. The treatment of immediate and secondary shock is by giving the heart something to act on, and this is done by subcutaneous or venous infusion of saline solution into the patient's system. Subcutaneous infusion is safer but takes a little longer to take effect. Venous infusion may cause pulmonary œdema or thrombosis. Fluid may also be given by the rectum and when possible by the mouth. The foot end of the bed must be raised and the patient's legs bandaged. Hot-water bottles must also be used but not to such an extent as to overdo the reaction and make the patient perspire too freely. Infusion with saline solution and adrenalin (1 in 20,000) is useful, for the adrenalin is a vaso-constrictor and therefore raises the blood pressure. If possible use oxygen with the saline treatment, as the hæmoglobin is so diluted that it wants oxygen to make more oxyhæmoglobin.

Meteorism is often preventable by using the flatus tube from the first. Distension can be detected without disturbing the dressings, or at most by simply undoing the many-tailed bandage. When detected give one grain of calomel every hour and a saline purge, or as an alternative a turpentine enema and leave in the flatus tube. A very good pill containing extract of belladonna, salol, and nux vomica increases peristalsis and so may be given with advantage. Once the intestine becomes distended with gas it becomes paralysed; then the medical attendant must look out for the quick thready pulse and give strychnine early. If other purges and enemata fail try a large enema of glycerine.

Peritonitis requires prompt treatment, such as a high turpentine enema, calomel and saline purges. Pay more attention to the pulse and less to the temperature when on the look out for peritonitis; if the pulse is under 100 the fear of this complication is usually groundless. As the toxæmia deepens the pain gets less and the surgeon must not be misled by this—the temperature also drops, which is again a deception to the unwary. If the peritonitis does not yield to the treatment mentioned an immediate second operation may be necessary under some local anæsthetic; two large tubes must then be put in and irrigation employed. In addition to this pints of saline solution may be allowed to gravitate into the subcutaneous tissues from a douche tin and free purgation kept up so as to flush the patient's system with saline solution. The more perfect the technique of the surgeon the less will he see of peritonitis after abdominal sections.

With regard to vomiting, anæsthetic vomiting is often due to an ether gastritis and is aggravated by previous frothiness, cyanosis, and strain on the right heart. The linen bag with Clover's inhaler to some extent lessens salivation and frothi- ness and is always cleaner than the rubber bag. Proper dieting before the operation is essential and gastric lavage before and after operation is useful in averting vomiting. While vomiting is going on the patient must lie in the right lateral recumbent position. For persistent vomiting gastric lavage is the best treatment, or 20 grains of sodium bicar- bonate in a tumblerful of water or three minims of tincture of iodine in a tumblerful of water may be given. Sips of iced champagne have also been found useful. For persistent hiccough try tongue traction or pressure on the phrenic nerve and perhaps a mustard leaf on the epigastrium. For the causes of regurgitant vomiting after gastro-enterostomy reference should be made to Moynihan's work on the stomach. If lavage, posture, and purgatives fail to relieve it an entero-anastomosis may have to be done and rectal feeding persisted in.

Post-operative hæmatemesis usually occurs during the first 48 hours, but may come on as late as the tenth day. It is usually seen after operations on the stomach, duodenum, and bile passages, especially in jaundiced cases, for here the blood seems to have lost its power of coagulation. The various causes are given in any work on abdominal surgery and are at present ill-understood. The treatment consists of gastric lavage with sodium bicarbonate or adrenalin. Calomel should be given frequently in small doses; also high rectal injections of hot water. To prevent this awkward and serious complication calcium chloride should be given in jaundiced and hæmophilic cases in large doses two or three days before operation.

Parotitis can in great measure be prevented by attention to oral asepsis. Stenson's duct is the most exposed one, hence the parotid gland is the one most frequently attacked. Depriving the patient of fluid is another cause of parotitis. The treatment is mainly palliative with attention to any septic focus. Glyco-thymoline or listerine are useful mouth washes.

Phlebitis and thrombosis after operations are caused by sepsis, anæmia, and pressure on the calves of the legs. It is more usually seen after pelvic operations, for the clot extends into the pelvic, iliac, and saphenous veins. The treatment is mainly palliative with lead and opium lotion, elevation of the limb, and the avoidance of pressure, movement, or rubbing.

Chest complications are more frequent after operations on the upper abdomen; for then the rigid lower intercostal and upper abdominal muscles allow an accumulation of bronchial secretion. The prolonged Trendelenburg position is bad in this respect. Other conducive agencies are cold and exposure, a dirty inhaler and rubber bag, and oral sepsis. The treatment is to prop the patient up, give ammonium carbonate freely, and use a steam kettle containing some Friar's balsam; also cover the patient's chest in a pneumonia jacket.

Post-operative mania and neurasthenia must be treated symptomatically and tactfully. Local suppuration may occur in any wound, say, for instance, a breast case in which there has been inefficient hæmostasis or drainage—a thrombus has formed and broken down. Here stitches have to be sacrificed and boric fomentations applied and good drainage substituted. If the wound is very dirty chlorinated soda solution or hydrogen peroxide is useful in cleansing it. In deep stitch suppuration if the suture is of unabsorbable material it must be removed or troublesome sinuses may persist for months.

The question of adhesions forming after abdominal operations is a most important one and must be borne in mind when vague pains still worry the patient months after the operation. This is often seen after appendicectomy and hysterectomy. The rational treatment in these cases is to get the bowels open early and to keep them open so as to stir up peristalsis. The position of the patient must be frequently changed so as to stretch any bands while they are yet thin and elastic. If this does not answer, the bands must be divided and, if possible, only peritoneal surfaces apposed to each other. If unrelieved, these bands may cause either acute or chronic obstruction.

Fæcal fistula is often seen after suppurative appendicitis and some hernia cases. The fistula should in most cases be left alone and it will close spontaneously within six months. Acute dilatation of the stomach is recognised by inspection and palpation and the patient's discomfort and irregular respiration. The symptoms are sickness, a small quick pulse, dyspnœa, and syncope. It may be due to pyloric spasm and hyperchlorhydria, atony either nervous or toxic, the dorsal position, and a too sloppy dietary. The treatment consists of lavage, calomel in small and frequent doses, and rectal feeding. Give alkalies.

The following are a few brief notes on certain operations. In some cases of colostomy the bowel will have to be opened after 48 hours—this must be done with asepsis, of course; trim up the redundant mucous membrane, and snip off any appendices epiploicæ if this has not already been done; the wound is then dressed with oiled silk or eucalyptus ointment spread on gauze. A wise precaution is to seal off the skin incision with "new skin" or collodion. The lower and stagnant part of the bowel should be flushed through or syringed out with boric solution so as to keep the bacillus coli in hand. Remember it is the atony of long-continued obstruction which causes the mortality of colostomy, not the operation.

In hernia cases get the bowels open early and so prevent adhesions. Scrotal hæmatocele is avoided by careful ligation, good drainage, and raising the scrotum. In using drainage-tubes about the scrotum do not forget the aseptic safety-pin, or these tubes may disappear and cause trouble and annoyance. Collodion and gauze is a useful dressing, especially in children. Vomiting coming on a week after the operation is either due to sloughing of an omental stump or to adhesions between it and the intestine.

In breast cases leave the arm free and use a many-tailed bandage. Nearly always leave a tube in for 24 hours and change the dressing as soon as it is "through." Dust the axilla well with boric acid.

In gall-bladder cases use cellulose wadding as the best absorbent for the bile from the fistula. A rubber drain is usually fastened to the gall-bladder by catgut sutures and will come away in eight days. Conduct all the bile into an air-tight glass vessel or into an antiseptic solution. After the tube is removed the skin may get sore from the digestive action of the bile on it; therefore wash the skin daily and dust it well with boric powder or smear it with hazeline ointment. The lumbar drainage-tube is removed in from 36 to 48 hours and a gauze drain substituted for a few days. If gauze is used in the anterior incision instead of or as well as a tube it is well to wait from 48 to 72 hours before gently withdrawing it, as it may be packed down on to an incision in the common bile-duct. Look out for hæmorrhage in all jaundiced cases and give calcium chloride before and after operation. The leakage sometimes seen after duodeno-choledochotomy is due to sutures near the ampulla of Vater having been prematurely digested by the pancreatic juice.

After operations on the urinary bladder give salol or boric acid. If the incision is suprapubic wash out the bladder thoroughly through a catheter per urethram and a tube per abdomen. The urine should be syphoned off and not allowed to escape into the dressings. Here, again, cellulose wadding is the best absorbent if syphonage cannot be thoroughly carried out. For hæmorrhage use liquid extract of hamamelis as an injection. After rectal operations eucalyptus ointment spread on iodoform or cyanide gauze is a good dressing for packing. If an enema has to be given after a rectal case give a cocaine suppository first, also an olive oil injection. For rectal hæmorrhage pass a catheter as flatus tube and then pack round it with a captive sponge. A morphine and belladonna suppository will often help the patient to micturate after a rectal operation; a purge is also useful, for the centres of the bladder and the rectum are close together in the spinal cord so when one works the other often follows suit. If there is difficulty in keeping a drainage-tube in any wound or organ affected by position or respiration anchor the tube to the skin by a silkworm-gut suture. After operations for suppurative appendicitis or other local peritoneal abscess when the initial gauze packing and tube have been removed do not syringe the wound but gently swab it clean and pour in boric powder. In knee-joint operations do not hesitate to sacrifice a stitch if there is tension or you may induce suppuration. In fracture of the patella never fix the knee-joint but begin passive and active movements very early. If the bone has been well wired the patient should be walking with sticks in a fortnight. In circumcisions never use strapping; just plenty of boric ointment on lint, with wool and a napkin. If the dressing sticks let the patient sit in a warm bath. After a few days carefully manipulate and coax the retracted skin on to the glans penis. In tongue cases rectal or nasal feeding is often necessary. Medicated steam kettles should be kept going and strict oral asepsis carried out. In dressing cases boiling water can always be got and should be used. Sterilise all instruments, dressings, and re-introduced tubes.

PHYSIOLOGICAL AND PATHOLOGICAL OBSERVATIONS ON WRIGHT'S METHOD OF TESTING THE BLOOD AND URINE,

WITH SPECIAL REFERENCE TO THE CONCENTRATION OF THE SERUM AND URINE (EXPRESSED IN TERMS OF NaCl) AND THE EXCRETORY QUOTIENT IN NATIVES OF BENGAL.

BY DAVID MCCOAY, M.B. R.U.I.,
CAPTAIN, I.M.S.; PROFESSOR OF PHYSIOLOGY, MEDICAL COLLEGE, CALCUTTA.

IN THE LANCET of April 2nd, 1904, Sir A. E. Wright and Dr. J. N. Kilner published a paper on a New Method of Testing the Blood and the Urine, with special reference to the Determination of the Excretory Efficiency of the Kidney, and in THE LANCET of Oct. 21st, 1905, another paper of absorbing interest appeared under the joint authorship of Sir A. E. Wright and Dr. G. W. Ross. This paper dealt more particularly with the discrimination of "physiological albuminuria" from the albuminuria caused by renal disease.

In the first of these papers the authors showed by this new method of testing the blood and urine that in health a relationship between the concentration of the serum and the urine exists of such a nature that the excretory quotient is never represented by a figure less than two but always by two or over. The second paper—which introduced a much simpler method of carrying out the test—was devoted to demonstrating by means of the excretory quotient test that in physiological albuminuria the kidneys are not organically impaired and are able to elaborate from the blood a concentrated saline solution.

Briefly, the test is as follows. In a capillary tube a measured volume of blood is mixed with two volumes of a diluted standard solution of NaCl; different dilutions $\frac{N}{30}$, $\frac{N}{35}$, $\frac{N}{40}$, &c., are made use of until the particular dilution is found that just exactly causes hydrolysis of the red blood corpuscles. Thus, for example, two volumes of a $\frac{N}{35}$ NaCl solution cause hæmolysis of one volume of blood—i.e., two volumes of a 0·167 per cent. NaCl solution cause hæmolysis of one volume of blood. Similarly the urine is taken (certain precautions in its collection being observed) and is diluted with distilled water four-, six-, eight-, &c., fold until it is again found that two volumes of the diluted urine when mixed with one volume of the blood just causes hæmolysis—i.e.,

Two volumes of $\frac{U}{12}$ cause hæmolysis of one volume of blood.

Therefore $\frac{U}{12} = \frac{N}{35} = 0{\cdot}167$ per cent. NaCl.

Therefore, urine = 2·004 per cent. NaCl = hæmosozic value of the urine—i.e., the urine contains the equivalent of 2·004 per cent. NaCl.

Again, the serum of the blood is examined in exactly the same way and its concentration in terms of NaCl is estimated as, for example:—

Two volumes of $\frac{\text{serum}}{6}$ cause hæmolysis of one volume of blood.

Therefore $\frac{S}{6} = \frac{U}{12} = \frac{N}{35} = 0{\cdot}167$ per cent. NaCl.

Therefore serum = 1·002 per cent. NaCl = hæmosozic value of the serum—i.e., the serum contains the equivalent of 1·002 per cent. NaCl.

The excretory quotient is obtained by dividing the minimum dilution of the urine that causes complete hæmolysis by the minimum dilution of the serum that causes complete hæmolysis; in the example this would be—

$$\frac{\text{Urine}}{\text{Serum}} = \frac{12}{6} = 2 \text{ (excretory quotient).}$$

In healthy Europeans in England this excretory quotient never falls below the figure 2, whereas in conditions of impairment of the renal function it falls to well below 2, usually 1 or under.

In the second paper mentioned above Wright and Ross showed that in physiological albuminuria the excretory quotient conformed to the standard obtained in health, in other words, that in physiological albuminuria the kidney is able to elaborate from the blood a concentrated saline solution, whereas in albuminuria depending on organic disease of the kidney it is unable to do so.

From the result of investigations on metabolism that have been going on for some time in the Physiological Laboratory, Medical College, Calcutta, it was evident that some modification of this test would be necessary when applied to natives of Bengal, and for this reason a series of observations was undertaken to obtain the data for the Bengali. Healthy students attending the department were examined. The method as devised by Wright was rigidly observed, so that the results might be as far as possible comparable. Besides the concentration of the serum and urine and excretory quotient a few other observations were made in each instance—viz., the blood pressure, the freezing point of the urine, and the chlorides in the urine—as is shown in Table I.

TABLE I.

No.	Solution of diluted normal NaCl causing hæmolysis.	Blood pressure in mm. Hg.	Hæmosozic value of serum in terms of NaCl.	Hæmosozic value of urine in terms of NaCl.	Freezing point.	Chlorides.	Excretory quotient.
			Per cent.	Per cent.	° C.	Per cent.	
1	$\frac{N}{37{\cdot}5}$	109	0·936	1·09	– 1·42	1·07	1·18
2	$\frac{N}{47{\cdot}5}$	105	1·84	1·84	– 1·49	1·13	1·00
3	$\frac{N}{40}$	115	1·02	1·16	– 0·97	1·1	1·14
4	$\frac{N}{40}$	98	1·02	1·16	– 2·03	1·08	1·14
5	$\frac{N}{40}$	100	0·87	0·87	– 0·87	0·83	1·00
6	$\frac{N}{45}$	115	1·04	1·75	– 1·80	1·72	1·68
7	$\frac{N}{52{\cdot}5}$	105	1·33	1·66	– 1·47	1·34	1·25
8	$\frac{N}{35}$	109	1·33	1·33	– 1·40	1·20	1·
9	$\frac{N}{50}$	88	1·75	1·63	– 1·43	1·37	0·93
10	$\frac{N}{40}$	102	1·27	1·75	– 1·24	1·70	1·32
11	$\frac{N}{40}$	105	0·87	1·16	– 0·89	0·97	1·23
12	$\frac{N}{40}$	114	1·02	1·16	– 0·85	0·82	1·
13	$\frac{N}{42{\cdot}5}$	97	1·23	1·37	– 1·50	1·42	1·11
14	$\frac{N}{40}$	114	1·02	1·16	– 1·16	1·14	1·14
15	$\frac{N}{35}$	110	1·33	1·33	– 1·17	1·24	1·00
16	$\frac{N}{45}$	106	0·910	0·910	– 0·90	0·87	1·00
17	$\frac{N}{40}$	100	1·02	1·02	– 0·93	0·78	1·00
18	$\frac{N}{45}$	98	1·04	1·04	– 0·75	0·65	1·00
19	$\frac{N}{43{\cdot}75}$	107	1·06	1·33	– 1·30	1·30	1·25
20	$\frac{N}{47{\cdot}5}$	103	0·98	1·47	– 1·38	1·31	1·50
21	$\frac{N}{67{\cdot}5}$	95	1·01	1·42	– 1·14	1·22	1·40
22	$\frac{N}{65}$	83	2·07	2·69	– 1·94	20·1	1·25
23	$\frac{N}{45}$	93	1·04	1·04	– 1·48	1·03	1·00
24	$\frac{N}{52{\cdot}5}$	97	0·89	1·33	– 1·57	1·50	1·50
25	$\frac{N}{52{\cdot}5}$	93	0·779	0·89	– 0·90	0·81	1·14

A large number of students were examined, of which the above tabulated results of 25 may be taken as typical examples, and we may conclude that the averages obtained do not depart far from the normal standards for natives of Bengal. All these observations were taken practically under the same conditions regarding weather, time of day, and interval after food and drink; the urine was collected during the process and the blood pressure was examined by the same instrument (Riva Rocci's), each student being placed in exactly the same position. In every instance also each particular observation, such as the freezing point of the urine, the chlorides, &c., was made by the same observer and in the same manner. An analysis of the results works out as follows:—

1. *Caste, age, condition, &c.*—All were healthy Hindus of Lower Bengal, their age varying between 20 and 25 years.

2. *Blood pressure.*—Riva Rocci's sphygmomanometer with Recklinghausen's broad armlet on the brachial artery—taking the reading at the disappearance of the pulse at the wrist—was the method employed. The pressure over a very large number of observations varied between 83 mm. Hg and 118 mm. Hg, the average being slightly *over 100 mm. Hg* (sitting position, arm level with heart). *This is much lower* than the blood pressure laid down for Europeans in European (colder) countries.

3. *The degree of dilution of standard solution of NaCl* necessary in order to cause complete hæmolysis of the red

blood corpuscles is greater than Wright obtained in England. $\frac{N}{35}$ is about the average which he lays down, whereas it will be seen $\frac{N}{45}$ is much nearer the true figure for natives of Bengal.

4. *The hæmosozic value of the serum*—i.e., the minimum dilution of the serum that causes complete hæmolysis multiplied by the percentage of the salt content equivalent of the blood. In the present series results practically identical with those published by Wright were obtained, so that we may take it that the serum in Europeans in England and the serum in natives of Bengal is practically the same—at least, so far as this method of investigation shows.

5. *The hæmosozic value of the urine*—i.e., the minimum dilution of the urine that causes complete hæmolysis of the red blood corpuscles multiplied by the salt content equivalent of the blood. This hæmosozic value of the urine was found to give very different results from those obtained in England. In Wright's published cases the hæmosozic value of the urine varied between 1·80 and 3·90 per cent. (expressed in terms of NaCl), while in natives of Bengal it varied between 0·87 and 2·69 per cent. NaCl, the average being much lower than in Europeans.

6. *The chlorides in the urine.*—As will be seen from Table I. there is a very close relationship between the amount of chlorides estimated chemically and the hæmosozic value of the urine expressed in percentage of NaCl. The average quantity of chlorides present in the urine by chemical analysis worked out to be 1·21 per cent., while the average hæmosozic value (in terms of NaCl) was 1·31 per cent. It will be evident that this amount (1·21 per cent.) of chlorides is lower than that obtained in Europeans.

7. *The excretory quotient*—i.e.:

$$\frac{\text{The hæmosozic value of the urine}}{\text{The hæmosozic value of the serum.}}$$

This differs very markedly from the results obtained by Wright. In the present series it varied between 0·93 and 1·63 compared with 2, or over 2, as seen in England. In natives of Bengal the figure representing the excretory quotient may be taken as normally about 1·20; it would therefore appear—as the hæmosozic value of the serum varies little from that of Europeans—that the urine of natives of Bengal requires much less dilution in order to cause hæmolysis than the urine of Europeans, and from this it would follow that the urine in natives of Bengal has a lower salt concentration than the urine in Europeans. This is sufficiently evident from a consideration of (*a*) the average quantity of chlorides; (*b*) the average freezing point; and (*c*) the average specific gravity, all of which are on a much lower grade than is the case normally in the urines of Europeans. This point has a distinct bearing on von Koranyi's criterion of renal competency—viz., whether the kidney is, or is not, competent to elaborate out of the blood a concentrated saline solution. Regarding this there will be fuller evidence when the pathological application of these results is dealt with.

8. *The freezing point of the urine.*—From an analysis of some hundreds of observations on the urine of healthy students it was found that the freezing point varies directly with the specific gravity. In the present series it varied between −81° and −2·23° C., but it very rarely was so low as −1·65° C., quite the common reading to find being −1° C. (about).

The quotient[1] $\frac{\Delta}{\text{NaCl per cent.}}$ representing the ratio of the total concentration to the sodium chloride in Europeans varies within relatively narrow limits in health, diet according to von Koranyi having practically no influence. In Europeans $\frac{\Delta}{\text{NaCl per cent.}}$ variations lie between 1·23 and 1·69, while in natives of India they lay between 0·72 and 1·78, very much wider limits than laid down for Europeans. In fact, in natives the quotient $\frac{\Delta}{\text{NaCl per cent.}}$ very nearly approaches unity, being just over or just under 1.

This investigation was undertaken with a view to obtain some idea of the condition of the blood and urine that normally is present in natives of Bengal. The following conclusions have been arrived at: 1. The excretory quotient in natives of Lower Bengal averages about 1·20 compared with 2 or more for Europeans. 2. The average blood pressure in the brachial artery is about 104 mm. Hg compared with 120 mm. Hg in Europeans. 3. The specific gravity and freezing-point differ widely from that obtained in Europeans, being much lower. 4. The total salts in the urine are low and the power of the kidney to elaborate out of the blood a concentrated saline solution would appear to be much less than in Europeans.

PATHOLOGICAL APPLICATION IN NATIVES OF BENGAL.

Wright, accepting von Koranyi's criterion of renal competency—the power of elaborating out of the blood a concentrated saline solution—was led to the conclusion from his results that by the excretory quotient test he was able to differentiate between conditions in which the functional activity of the kidney is impaired and those in which it is intact, even when there is albumin present in the urine; also that in the excretory quotient test we had obtained a trustworthy criterion of the competence or incompetence of the kidney. From the results obtained in pathological conditions in natives of Bengal a somewhat different conclusion has been arrived at. First with regard to the excretory quotient test in kidney disease the results obtained confirm those published by Wright as shown in Table II.

TABLE II.

No.	Blood pressure in mm. Hg.	Hæmosozic value of serum.	Hæmosozic value of urine.	Freezing point.	Chlorides.	Excretory quotient.	Remarks.
		Per cent.	Per cent.	°C.	Per cent.		
1	125	0·89	0·43	—	—	0·50	European. No œdema or ascites; anæmia present; albuminuria 1·3 per cent.
2	135	2·032	1·016	—	0·93	0·50	Well-marked Bright's disease; œdema and ascites present; albuminuria.
3	103	0·849	0·636	—	0·31	0·75	Slight œdema and albuminuria. Blood: Hb = 58 per cent.; r.b.c. = 3,370,000.
"	104	0·935	0·467	−0·71	0·68	0·50	
4	108	2·12	0·53	−0·92	0·38	0·25	Well-marked Bright's disease; albuminuria, œdema, &c. Blood: Hb = 42 per cent.; r.b.c. = 4,500,000.
5	100	4·26	1·16	−0·97	—	0·25	Œdema, ascites, albuminuria. Blood: Hb = 46 per cent. and 40 per cent.; r.b.c. = 2,100,000 and 2,400,000.
"	95	3·42	0·806	−0·82	0·54	0·23	

Hb = hæmoglobin; r.b.c. = red blood corpuscles.

Secondly, two cases of physiological albuminuria gave results exactly corresponding with those obtained in the normal series and fully agreeing with Wright's conclusions as shown in Table III.:—

TABLE III.

No.	Blood pressure in mm. Hg.	Hæmosozic value of serum.	Hæmosozic value of urine.	Freezing point.	Chlorides.	Excretory quotient.	Remarks.
		Per cent.	Per cent.	° C.	Per cent.		
1	87	0·81	0·935	−1·35	—	1·14	Albuminuria disappeared under treatment; had slight fever which may have accounted for the albumin.
2	112	0·83	0·83	−0·91	0·76	1·00	Albuminuria disappeared under treatment with $CaCl_2$ and rest.

The second of these cases had been looked on as a kidney case until his excretory quotient was tested. He was discharged from hospital cured.

---

[1] The letter Δ is usually employed to express the freezing point which is a measure of the total concentration of the solids in solution.

Thirdly, it has been found that the same low excretory quotient is obtained in certain of the secondary anæmias—such as ankylostomiasis—as in kidney disease, as shown in Table IV.

TABLE IV.

No.	Blood pressure in mm. Hg.	Hæmosozic value of serum.	Hæmosozic value of urine.	Freezing point.	Chlorides.	Excretory quotient.	Remarks.
		Per cent.	Per cent.	°C.	Per cent.		
1*	95	2·12	0·74	—	0·38	0·35	No albuminuria; œdema and ascites well marked and getting worse; very anæmic. Hb = 24 per cent.; r.b.c. = 2,080,000; normoblasts present.
,,	96	6·09	1·21	– 1·25	1·03	0·20	
2	86	3·95	1·23	– 1·33	1·12	0·41	No albuminuria; œdema and ascites present; anæmia. Hb = 21 per cent.; r.b.c. = 2,100,000.
,,	88	1·52	1·30	– 1·69	1·23	0·85	Improved; no albuminuria; no ascites, only a trace of œdema. Blood: Hb = 24 per cent.; r.b.c. = 2,500,000. Ankylostomiasis present.
3	122	1·72	0·934	—	0·73	0·60	No albuminuria; œdema and ascites present; anæmia. Blood: Hb = 48 per cent.; r.b.c. = 4,600,000.
,,	115	2·32	0·67	—	0·40	0·30	Patient worse; more œdema and more ascites. Blood: Hb = 44 per cent.; r.b.c. = 3,200,000. This was a case of ankylostomiasis.
4	88	0·847	0·47	– 1·25	0·95	0·56	No albuminuria; no œdema or ascites; diarrhœa. Blood: Hb = 22 per cent.; r.b.c. = 1,350,000.

* Post-mortem examination of this case showed ankylostomiasis with the presence of intestinal ulcers to be the cause of death. There was no disease of the kidneys.

Fourthly, the low value for the excretory quotient is not obtained in cases showing œdema and ascites due to some cause other than anæmia, as shown in Table V.

TABLE V.

No.	Blood pressure in mm. Hg.	Hæmosozic value of serum.	Hæmosozic value of urine.	Freezing point.	Chlorides.	Excretory quotient.	Remarks.
		Per cent.	Per cent.	°C.	Per cent.		
*1	107	1·022	1·164	– 1·30	0·75	1·13	Very marked œdema and ascites; no albuminuria; no anæmia. Blood: Hb = 97 per cent.; r.b.c. = 5,000,000.
,,	105	1·022	1·168	– 1·18	0·81	1·14	Œdema slightly diminished. Blood: Hb = 87 per cent.; r.b.c. = 4,670,000. P.M.: probable cause of death, wet form of beri-beri.

* The examination of this case would tend to show that œdema, &c., may be due to other causes than the retention within the tissues of the salts of the blood. In this particular instance the most probable explanation was the condition of the peripheral nerves.

From an analysis of the results shown in Table IV. it will be evident that, to explain the low excretory quotient present in cases of secondary anæmias in which the kidneys are healthy, some cause other than renal incompetency must be looked for. The published cases bearing on this point afford little information of value. In Wright's series[2] the serum is shown to be modified in the same characteristic manner as is seen in Table IV., but only in two instances was the value of the excretory quotient estimated. His results in pernicious anæmia and chlorosis would point to a greater degree of serum concentration in these diseases such as occurs in secondary anæmia and in the œdema of nephritis. Therefore, in pernicious anæmia and chlorosis we should expect to find the same low excretory quotient that is seen in the other conditions mentioned.

Upon this question the work done by Dr. T. Houston[3] throws considerable light. He shows that, in the œdema of renal disease, in chlorosis, in splenic anæmia, and in pernicious anæmia there is an abnormal accumulation of fluid in the blood and tissues and that the œdema of anæmic conditions results from a hydræmic plethora of the blood. Professor J. Lorrain Smith,[4] from investigations on the total volume of the blood in the different forms of anæmia, came to the conclusions that the anæmia of chlorosis is due to an increase in the plasma of the blood, the total hæmoglobin remaining normal in amount, whilst in pernicious anæmia the volume of the plasma may be reduced or increased. Professor Smith states: "The condition (chlorosis) may be described as consisting in a great increase in the plasma of the blood, the apparent loss of hæmoglobin being due almost entirely to the increase in the plasma." He also lays stress on the fact, noted by several observers, that the specific gravity of the plasma in chlorosis is the same as that of normal blood; this, it will be evident, has a very important bearing on the cause of the increase in the amount of plasma—viz., its increased salt concentration from retention of the chlorides. Further, it is well known clinically that *one of the first signs of improvement in these anæmias* is a loss of body-weight usually due to a great increase in the fluid excretions. There is ample proof that retention of chlorides involves a retention of water with an accompanying increase in body-weight, which increase will closely correspond to the theoretical amount necessary to give a dilution of about 0·55 per cent. of chlorides.[5] Taking all these different facts in combination with the work done on the salt interchanges of the body, it would appear that in the different forms of anæmia and in renal disease there is an increased salt concentration of the serum (salt retention) involving a retention of fluid within the *tissues*; this would equally explain the increase in body-weight, the hydræmia and increased volume of the blood, the œdema and anasarca which is such a common feature and, at the same time, it would explain the results obtained by the excretory quotient test in the anæmias examined in Table IV.

Now the question arises, What is the cause of this retention of chlorides and increased salt concentration of the serum? Widal, who was the first to work on this subject, ascribed the condition to "renal impermeability" to chlorides. This view would lay the fault with the excretory function of the renal epithelium and would therefore be on a par with von Koranyi's criterion of renal competency—the power of elaborating from the blood a concentrated *saline solution*; but "renal impermeability" due to kidney disease will not explain the retention of chlorides in anæmia where the renal function is not impaired and where, when improvement begins, the elimination of the chlorides may set in suddenly, the increased *salt concentration of the* serum disappearing rapidly and along with it the œdema, ascites, &c. In pneumonia and in other febrile diseases there is retention of the chlorides. Hutchinson has shown that the tissues in these diseases contain chlorides in excess although the kidneys are perfectly healthy. From this and other evidence it seems probable that a retention of the chlorides occurs quite independently of the kidney, and that, therefore, Widal's term "renal impermeability" is not a true explanation of the condition. Forster has given a purely physical explanation of the phenomenon. He believes that crystalloids in the blood may exist in *two states*: a small part free and able to pass through the glomerular epithelium and a larger part in combination with colloid and unable to pass through the glomerulus. The increased salt concentration of the serum in nephritis and anæmia could *easily* be explained on this theory by the supposition that in these conditions there was an increase in the salt-combining *colloid material* present in the tissues.

It might be suggested, therefore, that the high degree of concentration of the serum in nephritis or, at least, in anæmia may be due to some change in the condition of the blood—such as loss of hæmoglobin, diminution in the number of the red blood corpuscles or both combined—that so affects the relationship between the salt retained in combination with colloid and the salt free to be eliminated that a much larger proportion of the salt is retained than in normal circumstances. This view would exonerate the kidneys from blame and lay the fault on the condition of the blood. What evidence is there in favour of this view? In the first place, it is a remarkable fact that it is in the chronic parenchymatous form of nephritis that the salt retention and low excretory quotient are best seen, and it is in this form also that the anæmia of Bright's disease is well marked. Then from an analysis of the results of observations in anæmic conditions due to different causes the concentration of the serum varies directly with the amount of œdema present and with the degree of anæmia, as shown in Table VI.

TABLE VI.

Date.	No.	Concentration of serum.	Concentration of urine.	Excretory quotient.	Remarks.	Blood.
		Per cent.	Per cent.			
13/3/07	1	4·26	1·16	0·25	Albuminuria; marked œdema and ascites.	Hb = 46 per cent.; r.b.c. = 2,100,000.
18/3/07	,,	2·84	1·42	0·50	Œdema and ascites much less.	Hb = 40 per cent.; r.b.c. = 2,400,000.
21/2/07	2	2·12	0·74	0·35	No albuminuria, œdema and ascites present.	—
26/2/07	,,	6·09	1·21	0·20	Œdema and ascites much worse.	Hb = 24 per cent.; r.b.c. = 2,050,000.
6/3/07	3	3·95	1·23	0·41	No albuminuria, œdema and ascites present.	Hb = 21 per cent.; r.b.c. = 2,100,000.
17/4/07	,,	1·52	1·30	0·85	No œdema; no ascites.	Hb = 24 per cent.; r.b.c. = 2,700,000.
8/3/07	4	0·84	0·63	0·75	Albuminuria; slight œdema.	Hb = 58 per cent.; r.b.c. = 3,370,000.
16/3/07	,,	0·935	0·46	0·50	Œdema better marked; urine scanty.	Hb = 56 per cent.; r.b.c. = 3,450,000.
6/3/07	5	2·12	0·54	0·25	Well marked Bright's disease; œdema and ascites.	Hb = 42 per cent.; r.b.c. = 4,500,000.

These results contrast very markedly with those shown in Table V., in which, even with general œdema and ascites but no anæmia, the concentration of the serum and excretory quotient conformed to the normal. Of course, a much larger number of observations will be necessary before any definite conclusion can be arrived at, but all our evidence would seem to point to the fact that the degree of concentration of the serum determines the degree of œdema, and that there is some relationship between the œdema and the amount of anæmia. This appears to be true equally for secondary anæmias (probably also all anæmias) and the anæmia of Bright's disease.

It would, therefore, follow that the excretory quotient test, being a measure of the salt concentration of the serum compared with the salt concentration of the urine, does not depend on the presence or absence of kidney disease, whereby the kidney is unable to eliminate the chlorides, but does depend on some condition of the blood or tissues by which chlorides are retained in the system. What the determining factor in this retention is at present it is not possible to say; it would appear at least to have some relationship to the presence and degree of anæmia, but whether due to destruction of corpuscles, loss of hæmoglobin, or some other factor must remain for the present an open question.

Methods of investigation.—When dealing with blood containing a low percentage of hæmoglobin a modification of Wright's method had to be adopted, as in these cases the colour changes on dilution differ so slightly that precision could not be attained. The translucency of hæmolysed blood was taken advantage of and the point where hæmolysis occurred was determined by the ease with which a black dot on a white ground could be seen through blood that had been hæmolysed compared with the non-translucency of even very diluted blood that had not undergone hæmolysis.

In each observation the blood examination was carried out by an independent worker, Assistant-Surgeon L. M. Ghosal, L.M.S.; also the amount of chlorides present in the urine was determined by another assistant, Assistant-Surgeon M. M. Dutta, L.M.S., to both of whom I offer my best thanks for much assistance.

For permission to examine the different patients I am indebted to Colonel C. P. Lukis, I.M.S., principal; and Colonel G. F. A. Harris, I.M.S., Captain J. W. D. Megaw, I.M.S., and Captain M. MacKelvie, I.M.S., physicians of the Medical College Hospital, Calcutta. Last, though not least in degree, my thanks are due to the students of the physiological classes for providing the means of determining the physiological standards on which the whole value of the paper rests.

Calcutta.

CASE OF MULTILOCULAR OVARIAN CYST SUCCESSFULLY REMOVED FROM AN INFANT AGED 11 MONTHS.

BY CHARLES WATSON MACGILLIVRAY, M.D. EDIN., F.R.C.S. EDIN.,
SENIOR ORDINARY SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

THE following case seems to possess some points of interest, in fact to be perhaps unique in certain respects, and therefore deserves to be recorded.

Towards the end of January of this year an infant was sent to my wards in the Royal Infirmary, Edinburgh, as a case of tuberculous peritonitis requiring surgical interference. The mother, a woman aged 35 years, gave the following history. When she was about 20 years of age she married and had one child, a boy, who died. She was afterwards left a widow, but subsequently she again married and had five consecutive miscarriages, at periods varying from four to seven months. No syphilitic history could be made out. Finally, at the commencement of February, 1906, she was safely delivered, at full term, of a healthy female child who was entirely brought up on the breast. The child throve well until she was three months old. The mother then noticed that the abdomen was hard and full, and that the infant seemed to suffer pain and discomfort, and was occasionally sick and troubled with diarrhœa. From this time onward the abdomen rapidly increased in size, while the child wasted. She grew peevish and took nourishment badly, had increasing difficulty in breathing, and the former symptoms of digestive disturbance got steadily worse. The mother finally sought medical advice, and the child was sent to the Infirmary with the diagnosis previously mentioned.

On admission the child was found to be an ill-nourished and emaciated infant, with cyanosed lips and face, rapid pulse, difficult breathing, and some sickness and diarrhœa. The abdomen was enormously distended, the lower ribs were projecting, the parietes were thinned and showing numerous large distended veins, and the navel was projecting. The whole abdomen was of drum-like hardness, so that nothing could be felt of its contents. There was absolute dulness on percussion, except in the left flank, where there was a tympanitic area. Slight, varying areas of tympanites could be made out on light percussion to the right of the umbilicus. The dulness extended up to the right nipple, and a circumscribed area of tympanites was to be made out below the left nipple. About a tablespoonful of clear yellow fluid was drawn off by means of a hypodermic syringe from the right flank and half a teacupful of similar fluid from the left of the umbilicus. The fluid did not flow easily; on moving the needle in different directions it seemed to penetrate separate cavities. The distension being slightly relieved, the surface of the underlying structures appeared to be irregular and nodular. No more definite diagnosis could be made than that the abdomen, from the diaphragm to the pelvis, was filled by a mass containing separate cavities filled with fluid, and that the greater part of the intestines lay in the left flank with a single coil passing upwards to the right of the umbilicus.

Two days later the child was chloroformed in a warm theatre and an exploratory incision was made a little to the left of the middle line below the umbilicus. The abdominal cavity being opened a small quantity of ascitic fluid escaped and the nodular wall of a large cyst was seen. This was punctured, but as the cavity proved to be multilocular only small quantities of fluid escaped and no appreciable diminution in size resulted. Passing the finger into the cyst and trying to break down the septa gave no better result, but the cyst seemed to be nowhere firmly adherent to the abdominal parietes. The child was now very much collapsed, but, as it was evident that death would result if nothing more were done, the incision was rapidly extended upwards to within two inches of the ensiform cartilage. On the front of the multilocular cyst, to the right of the umbilicus, there was now to be seen the cæcum with the appendix, and the ascending colon lying empty, attached to the front of the cyst and stretched over it. The cyst was therefore evidently retroperitoneal. Avoiding these structures the posterior layer of peritoneum was torn through and stripped off the cyst, which was then rapidly turned out. There were found three points of attachment to the posterior abdominal wall—one below the liver, one about the level of the umbilicus, and a third near the brim of the pelvis to the right side. These were made up of large veins and arteries which, after being seized with forceps, were divided, the tumour was removed, and the points of attachment were ligatured. The child was now pulseless, and the breathing for the moment was imperceptible from shock. On artificial respiration being had recourse to the breathing, however, rapidly improved, the chest being now able to expand, and the pulse improved. The abdomen was dried out and hot saline solution was introduced. The state of the child did not allow of any prolonged investigation as to the condition of the pelvic or other organs and the long incision, some eight inches in extent, was rapidly sutured with a continuous suture, sterile wool and a firm bandage being applied as dressing. The infant was put to bed in a collapsed condition and was surrounded by hot bottles. More or less collapse continued throughout the night, the child refusing milk but taking minute doses of whisky with avidity. The next day the child took the breast and never thereafter had a bad symptom. The wound healed by first intention and the suture was removed at the end of ten days, the walls of the abdomen being supported by means of broad strips of adhesive plaster, cotton-wool, and a firm bandage.

The tumour was found to be a curious double multilocular cyst, the two halves being nearly equal in size and attached by their fibrous walls the one to the other by loose connective tissue. Its length on removal was about 10 to 11 inches and its thickness about four to five inches. It filled up the whole distended abdominal cavity from the diaphragm to the true pelvis, and from its size it came to be a question whether the cyst was removed from the child or the child from the cyst.

The pathological report, kindly supplied me by Mr. Henry Wade, the conservator of the museum of the Royal College of Surgeons of Edinburgh and assistant pathologist to the infirmary, is as follows:—

> *Report on specimen.*—Tissue consists of a stroma of young connective-tissue cells, forming young fibrous tissue. These surround spaces which have an epithelial lining which is flattened out in some, absent in others, and in others is seen to be undergoing a mucoid degeneration. Multiple cystic ovarian tumour.

On consulting the literature, I find that perhaps the most complete and full *résumé* of the subject of such tumours in children is that by Dr. Howard Kelly, of Baltimore, in the fifth volume of Keating's "Cyclopædia of the Diseases of Children," being a supplement published in 1961. Bland-Sutton also in his "Surgical Diseases of the Ovaries" goes pretty fully into the subject. There are also numerous individual cases reported in the medical journals.

De Sinety in 1875 was one of the first to call attention to the relative frequency of cystic ovaries in children. The investigations of Kissel in 1891 showed these to be mostly of the nature of cystic follicles, and pointed out that they were rare after the first year and were not to be confounded with adenocystomata, which make up a large proportion of the ovarian tumours of later childhood. In 1876 Professor C. Hening published an important treatise on the "Diseases of the Genital Organs in Children," and alluded to ovarian disease in childhood. In 1888 Alban Doran reported the occurrence of congenital double ovarian tumours in a seven months fœtus which only survived its birth a few minutes.

Bland-Sutton in his article on Ovarian Tumours in Infancy and Childhood reports 100 cases of ovariotomy in children under the age of 16 years, and gives statistics as to the mortality of the operation.

Howard Kelly, in his instructive article previously referred to, classifies ovarian tumours in children into cystic and solid—the former comprising the adenocystomata, the unilocular cysts and the dermoids and teratomata; the latter, the sarcomata and the carcinomata—and he specially points out that, in the case of children under three years, most ovarian tumours are either dermoids or sarcomata. After that age the large proportion, in fact one-half of all the cases of ovarian disease in childhood which have been reported, proved to be adenocystomata with a few monocysts. Dermoids and teratomata, he points out, are usually small or medium in size, or affect only one loculus of an adenocystoma. As to the question of differential diagnosis this is always difficult, cystic kidney, sacculated peritoneal exudation, hepatic and hydatid cysts being the conditions most likely to be mistaken for ovarian tumours. Retroperitoneal disease is not so likely to lead to difficulty, being generally a fixed sarcomatous tumour with a broad base springing from the pelvis. The most interesting part of Howard Kelly's article, however, is a very full list of operations for ovarian disease performed in children. From this one sees that under the age of four years the mortality has been 50 per cent. uninfluenced by the nature of the tumour. In older children the prognosis is good, though here, of course, the nature of the tumour is of importance. The list comprises 126 cases. Of these, 55 were cysts, multilocular or unilocular, with four deaths; 47 were dermoids, with ten deaths; of solid tumours there were 24, with eight deaths. Of the cysts, the youngest patient is one described by D'Arcy Power in 1898. The age was four months, the cyst was large but unilocular, with a long, thin pedicle, and the little patient made a good recovery. The next four mentioned are one by Alcock in 1871; a multilocular cyst with adhesions, in a little girl of three years. Death followed the operation. Another by Boldt in 1888, a suppurating cyst in a little girl of four years, a fatal result ensuing; a third fatal case by Boer of New York, in a child of four years; and, finally, Schwartz removed an adenocystoma from a child of four years with a good result. With one exception, in the case of a girl of nine years, all the other 51 patients recovered, they being all children over four years of age.

From the foregoing it will be seen that the case here recorded presents various points of interest. 1. The age of the patient at the time of operation was 11 months, the tumour having been first noticed at the third month. D'Arcy Power's case is therefore the only younger case recorded, the patient being four months old at the time of operation; but in his case the cyst was unilocular, with a long pedicle, and was easily removed through a small incision. 2. The enormous size of the tumour and the fact that though it formed one mass it was in reality made up of two multilocular cysts with flattened sides attached the one to the other by loose connective tissue, thus raising the question of its being a double ovarian cyst; the state of the child at the time of the operation prevented investigations being made as to the presence or state of the other ovary. 3. The retroperitoneal position of the tumour, as shown by the appendix, cæcum, and ascending colon lying in front of it and stretched over its surface, and the fact that the posterior layer of the peritoneum had to be torn through in order to enucleate the tumour. As Kelly states, such a position points to the tumour being sarcomatous and directly contra-indicates an ovarian origin. 4. The uneventful recovery of so young a child from such a severe operation.

Edinburgh.

A FURTHER NOTE ON RINNE'S TEST.

BY RICHARD LAKE, F.R.C.S. ENG.,

SURGEON TO THE ROYAL EAR HOSPITAL.

IN the preliminary note on Rinné's test which I contributed to THE LANCET[1] six primary divisions into which I suggested that Rinné's test should be subdivided were given; perhaps the whole intention was not sufficiently clear. The subdivision was not done with the idea that other means of subdividing the test would not be found, perhaps more easily applicable than those I suggested, and the reading of Dr. D. M. Mackay's letter,[2] referring to the means adopted by Professor Politzer of diagrammatically expressing the variations which might occur, has much interested me. For purposes of comparison I think, however, they will prove themselves very suitable. It is my belief that the terms "negative" and "positive" are themselves somewhat confusing, as there is no guide to enable the casual employer of these tests to remember accurately or definitely what is negative and what is positive Rinné. There are not wanting evidences to show that we are gradually tending more and more towards a re classification of diseases of the middle ear. We are coming more and more to regard obstruction of the Eustachian tube, with its resulting conditions of adhesive processes, hypertrophic thickenings, and fixation of the ossicles (short of bony ankylosis), as primarily the same disease, its varying symptoms being due to relative intensity of, and its subjective symptoms especially due to extension inwards of, the same pathological condition.

---

[1] THE LANCET, Feb 23rd, 1907, p. 505.
[2] THE LANCET, April 13th, 1907, p 1040.

Rinné α.—This subdivision includes all cases in which the bone conduction is normal, and in it the acoumeter is diminished while the voice is heard relatively well. The acoumeter is diminished in proportion to the loss of air conduction; the whisper is much reduced, but tuning forks are heard through the whole scale. Such cases are due to Eustachian obstruction, combined in the graver instances, as shown by increased loss of air conduction, with a certain amount of middle-ear disease. The completeness of the loss of the whisper, with a normal bone conduction, is, I believe, against the disease being one of primary nerve lesion. In rare circumstances one will find also examples of otosclerosis coming under this and the next headings, cases which stand midway between the increased and diminished bone conduction groups of this disease.

Rinné β, in which bone conduction is normal, air conduction absent, with a Rinné negative, appears to me to be a rare condition in which some gross lesion of the internal ear has occurred, but in which at least the middle part of the cochlear terminal division of the auditory nerve has escaped complete destruction.

Rinné γ, with bone conduction increased, air conduction normal, and a Rinné positive result, will yield cases of which the greater proportion will be early cases of otosclerosis having a plus bone conduction, though it is also possible that subacute inflammations of the middle ear may at times give this result, if the inflammation is confined largely to the region of the promontory. The latter condition, however, does not appear to be equally frequent with the former.

Under *Rinné δ* we have a large group of cases in which will be found a certain proportion yielding a positive result, though the majority will be Rinné negative. In these, the greater the increase in bone conduction the greater proportionately will usually be the loss in air conduction. The acoumeter will be diminished, the whisper generally almost lost, and the voice diminished, all in proportion to the loss of air conduction, and there will also be a loss of one or more octaves in the bass. In some instances the whole of the bass will be lost and at times the highest octave in the treble, whilst paracusis Willisii is a frequent symptom. Thus Rinné δ is pathognomonic of otosclerosis without further testing, in that form probably in which there are patches of rarefying osteitis in the labyrinthine capsule, fixation of the stapes in the oval window in these cases being indicated by a higher grade loss of air conduction.

Rinné ε.—In these cases the bone conduction is reduced, whilst the air conduction remains normal, the voice is but slightly interfered with, and there is but little interference with the tuning forks as heard by the air—that is to say, that although there may be general diminution, yet they are all heard, but the whisper is reduced, together with the acoumeter, the reduction in both being practically equal. As these conditions are rarely complained of or come before the aurist until the loss in bone conduction is at least ten seconds, I consider that they should be classed as early nerve lesions.

Rinné ζ.—These cases will, as I suggested in my preliminary note, like the δ group, be found to consist of cases yielding sometimes positive and sometimes negative results. The great majority of the slight cases is due to Eustachian obstruction with a negative reaction, with pronounced involvement of the middle ear, and I consider that, as a regular rule or hypothesis, one may assume that when the loss of bone conduction is over ten seconds a nerve lesion has become definitely established, as is also probably the case when the result is positive and the loss of bone conduction is less than ten seconds. The remaining cases present in this group are those of otosclerosis in which the bone conduction is minus. In other words, we have in this last group cases showing early involvement of the nerve elements secondary to middle-ear affections or obstruction of the Eustachian tube, many cases in which the nerve cannot be proved to be definitely involved, together with a large group of grave cases of otosclerosis.

Cases may present themselves, occurring chiefly under the ζ, and sometimes under the α, which belong to an entirely different category from any of those which we have seen and to which I have alluded elsewhere.[3] I refer to that class of cases in which neurasthenia has exerted a considerable influence. Group ζ may be extended so far that air conduction is entirely absent. These will be cases of gross nerve lesions. In the same way, under δ, one can find cases in which the air conduction is also entirely lost, the most advanced stage of that description of otosclerosis, cases of long-standing and in elderly people.

Having now thus far expressed my views as to the conditions which occur in the various subdivisions, it is quite evident that without a careful record as to the relative proportions of loss or increase in the bone conduction to the air conduction, Rinné's test alone is of small value, and that the advances which have been made in the instruments we have for testing hearing and the increase in our knowledge necessitated a further subdivision of the test, and its definite alteration into a proportional test. It is also shown, I think, that the more one devotes oneself to the study of these problems the more conclusively one can state the conditions present; but it seems to me it must be admitted that it demonstrates with equal clearness the need for a further test for differentiating between early nerve cases and slight affections of the middle-ear consequent upon or following Eustachian obstruction. Pathological research, combined with accurate estimation of the hearing powers, will no doubt shed light on some of the more abstruse questions but until these investigations have been made, and their results digested and assimilated, hypothesis must frequently take the place of fact.

Harley-street, W.

"CONGENITAL PILES."

NOTES ON THREE CASES IN WHICH A PILE LIKE CONDITION WAS NOTICED FROM BIRTH.

BY F. VICTOR MILWARD, M.B., B.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, CHILDREN'S HOSPITAL, BIRMINGHAM.

SINCE both external and internal hæmorrhoids are very rarely seen in young infants it appears to me to be worth while to place on record three cases of a pile-like condition which I have observed within the last 18 months in my out-patient practice at the Children's Hospital, Birmingham. These children were from 11 weeks to four months and the trouble was in each case stated by the mother to have existed from birth. I have seen also a fourth case in a child, aged two years, but as its similarity to the other three cases is somewhat doubtful I am not describing it here.

Although the disease is a trivial one, consisting of a single pile-like tumour of about the size of a large pea in the exact mid-line at the anterior margin of the anus, I am nevertheless inclined to think that we have here something of the nature of a congenital malformation rather than an outgrowth originating in a dilated venous radicle. The tumour occupies a situation on the perineum, encroaching on the anal canal, but in no way situated within it as is to some extent an external hæmorrhoid. I have seen one case of a thrombosed external hæmorrhoid in a child, aged three months, but it in no way resembled these cases, while the cutaneous tabs left by external hæmorrhoids are generally numerous and situated nearer the anal passage than the cases I am now describing. When snipped away with scissors very little bleeding results and the growth is seen to consist of fibro-fatty tissue. In one case ulceration was present and had destroyed a considerable portion of the growth. In the other two cases there was no ulceration or œdema and no fissure was present in the anal passage in any case. There were no signs of syphilis or malignant disease in any of the cases. In one case the anus was definitely narrowed, scarcely admitting the little finger, a fact supporting the congenital theory.

---

[3] West London Medico-Chirurgical Journal, 1905.

CASE 1.—The patient was a male child, aged 11 weeks. There was a tumour of the size of a large pea, soft in structure and not inflamed, situated at the anterior margin of the anus, its posterior margin being flush with the anal canal. The latter was slightly narrower than normal, and I dilated it with the finger. The mother stated that the little lump had been present since birth and was giving the child pain. It was removed with scissors.

CASE 2.—The patient was a female, aged four months. The tumour was situated in the same place as in Case 1 and was of about the same size. It was partially destroyed by ulceration and was somewhat indurated for the same reason. No stricture of the anus was present. The growth was snipped off.

CASE 3.—The patient was a female, aged 11 weeks. The pile was in the same place and was of about the same size as in the other two cases. Its structure was perfectly healthy and consisted of fibrous and adipose tissue. It was snipped off, as the mother complained of the pain which it was causing the child. I put this down entirely to her imagination, as there seemed no reason for painful symptoms to be present.

I think these cases deserve some distinctive title because they appear to me to be unlike any pile or anal tumour which I have seen described in text-books on rectal or general surgery. The tumour is single, median, exists from birth, is composed of quite healthy tissue, unless secondarily inflamed, and is not associated with any other morbid condition which might have produced it. The term "*hæmorrhoid*" is hardly suitable if it has not originated in a blood-vessel but it might well be designated the "congenital pile," since, as far as I am aware, no such condition has been hitherto described.

Birmingham.

A CASE OF TUBAL PREGNANCY ASSOCIATED WITH OVARIAN CYST.

BY E. G. EMERSON ARNOLD, M.B., B.S. DURH., M.R.C.P. LOND.,

COLONIAL MEDICAL SERVICE, FIJI; FORMERLY SENIOR OBSTETRIC HOUSE PHYSICIAN, ST. THOMAS'S HOSPITAL, AND REGISTRAR TO THE HOSPITAL FOR WOMEN, SOHO, LONDON.

So long as the etiology of ectopic gestation remains obscure and the influence on its production which other morbid conditions of the pelvic organs may exert is undetermined, it seems desirable to place on record any example of the condition which presents at all uncommon features. This consideration prompts me to report the following case, to the recital of which some added interest and some excuse for its shortcomings may also, perhaps, attach from the fact that it is a record of work carried out under many disadvantages in a remote part of the world.

The patient was a European woman, aged 27 years, and had been married for six years. She had had no children but there had been one pregnancy some four to five years ago which resulted in an abortion at the third to fourth month. After that she suffered from symptoms suggestic of pelvic trouble and was twice curetted in a hospital in Sydney. I first saw her in August, 1905, when she consulted me for pain in the back and left iliac region and for irregular menstruation. On bimanual examination at that time I found that the uterus was normal as to size and position but with its mobility slightly impaired, and movement of it by the examining finger applied to the cervix caused some pain. The right appendages appeared to be normal. The Fallopian tube could be rolled between the fingers and felt of natural size, while the ovary could be well defined and showed no enlargement. On the left side the ovary lay rather low and was slightly tender, though not apparently enlarged, but the tube felt thicker than normal and its palpation elicited pain. A diagnosis of chronic salpingitis of the left side was made and rest, hot douches, and other palliative measures were advised, as neither general nor local conditions seemed to warrant operative interference. The symptoms subsided under this régime and after a few months the patient ceased to regard herself as an invalid, though I impressed upon her the necessity for care as to chill and fatigue and at the menstrual periods.

I did not see the patient again until April 15th, 1906, when I received an urgent summons. On arrival I found that whilst dancing on the previous evening she had been very suddenly seized with acute pain in the left iliac region and had fainted. She had been put to bed and hot fomentations applied by her husband, when the pain soon ceased and she fell asleep. She was awakened, however, in the early morning by a return of the pain which again subsided. Inquiry elicited the facts that after unusual freedom from the former symptoms for some months and fairly regular menstruation, there had been complete amenorrhœa for six weeks. She had not, however, supposed herself pregnant as the catamenia had been irregular before. The breasts were slightly full and a drop of clear fluid could be expressed from the nipples. Bimanual examination, conducted with great gentleness, revealed a rounded swelling on both sides of the pelvis, the exact limits of which, as also the size of the uterus, I did not attempt to define accurately in view of the undesirability of bringing pressure to bear on the parts. The cervix was not noticeably soft. The os was not dilated and there was no vaginal hæmorrhage. The left rectus muscle was rigid but the abdomen was otherwise natural on gentle palpation. There were no general constitutional symptoms and the pulse and temperature were normal. A diagnosis of tubal pregnancy, probably unruptured but commencing to abort, was made; and surgical measures on the spot being out of the question, the patient was immediately removed with great care to the centre of the district where there is a plantation hospital.

Abdominal section was performed as soon as the necessary preparations could be completed, two European (unqualified) plantation hospital superintendents helping me as anæsthetist and assistant. An ovarian cyst of the size of a tennis ball was then found on the right side and an unruptured tubal gestation on the left. The abdominal ostium of the gravid tube was patent but not patulous, and a very small quantity of recent clot was lying amongst the fimbriæ. The right Fallopian tube appeared healthy, though it and the cyst were somewhat adherent to surrounding parts. The pregnant tube also was bound down by adhesions, some of them dense and obviously of old standing. The corresponding ovary was to all appearances normal. The tumour on the right and the swollen tube on the left were separated and removed in the usual way, but the ligatures were so applied as to leave *in situ* the right Fallopian tube and the left ovary, as neither showed any obvious lesion. During separation of the adhesions the cyst wall ruptured and there was some escape of its clear fluid contents into the peritoneal cavity. Some oozing occurred from the pelvic floor where adhesions had been separated and was not completely checked by douching with hot sterilised saline solution. With a bad light this led to considerable and annoying prolongation of the operation. It was ultimately stopped by sponge pressure and the application of adrenalin solution, though the action of the latter was somewhat disappointing. As in spite of a strong full pulse there was no sign of bleeding when the sutures had been put in, the abdominal wound was completely closed. The operation was well borne, recovery was rapid and uneventful, and the patient is now, one year later, in excellent health and menstruating regularly.

Only naked-eye examination of the parts removed wa possible. The ovarian tumour was unilocular and had th usual appearance and relations of an oöphoritic cyst moderate size. No corpus luteum of pregnancy was visib on section of the unaltered part of the viscus. The grav tube on section showed a typical tubal mole. The amnio cavity was distinct, but no embryo could be discerned. T mole was of rounded shape, of about the size of a la walnut, and situated at the junction of the middle and o thirds of the tube.

It would have been easy, indeed far easier, to remove healthy right tube and left ovary; but I venture to thi was good practice to leave both. A premature menopau always undesirable and particularly so in a climate w though healthy for the tropics, seems to have a spe trying effect on the nervous system. Moreover, it think, been shown that an ovum from one side ca its way to the Fallopian tube of the other. The should thus be not hopelessly debarred from natural hood, and the chances of further disease or accident to me insufficient to justify the sacrifice of apparently organs.

Was the ovarian cystoma a mere coincidence or ha influence in determining the intratubal detention ovum? I felt no trace of it at the examination m months previously, and as I was then able to pal ovary distinctly I can confidently state that it did not then exist in tangible form. Both history and vaginal examination pointed to prior salpingitis of moderate degree of the tube which became pregnant, while the healthy right tube adjacent to the tumour was free. Increased vascularity of the pelvic viscera consequent upon the pregnancy would doubtless explain the rapid growth of a previously small, or even latent and potential, cyst in the ovary.

Improved methods of diagnosis and more frequent operations have demonstrated that extra-uterine cyesis is by no means so rare as was thought at one time; and diversity of race and modes of life would not seem to have much influence on its frequency. During three years' official and private practice in this particular district of Fiji, among a limited but polyglot community, I have met with three other instances of it besides the one here related. The diagnosis was confirmed in two of these cases by operation after rupture and in the third post mortem, the patient having succumbed immediately after admission to hospital. In each case the Fallopian tube was the site of the pregnancy.

Some authorities have denied that prior salpingitis is an etiological factor, considering that a healthy tube is more likely to become the nidus of an ovum than one the lining membrane of which is altered by disease. But the frequency with which a clear history of former tubal inflammation can be obtained from the subjects of ectopic gestation is so great that it is difficult to resist the conclusion that it must play an important if not essential rôle in the production of this abnormality. Out of a good many cases of the kind which I saw in the past at hospitals in London with which I was connected I cannot call to mind one of which this was not true and my four patients have all had a history indicative of former tubal disease. Of these women one was, like the subject of this paper, a European; the others were Hindu coolies (indentured immigrants). The latter class do hard outdoor work in the sugar-cane fields in all weathers and gonorrhœa is very prevalent among them. I have successfully removed suppurating Fallopian tubes from three of them in this part of Fiji and I have seen many others with symptoms and physical signs of salpingitis. I have not met with a case of ectopic gestation in a native woman, and I do not think that one has ever been observed. Their disinclination to apply for European medical aid would, however, account for this; and inquiries among them lead me to think that the Fijian woman is, like her sisters of other complexions and in other lands, occasionally the victim of this catastrophe.

Labasa, Vanua Levu, Fiji.

ON THE

VALUE OF THE HIGH-FREQUENCY SPARK AS A LOCAL APPLICATION.

BY E. REGINALD MORTON, M.D. TORONTO,
F.R.C.S. EDIN.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT OF
THE LONDON HOSPITAL.

IN July, 1904, a medical man came to me to ask if I would apply the high-frequency current to his head for alopecia areata. He had suffered from this for several years and had tried everything ever suggested for this disease and concurrently had consulted and followed the advice of most of the more eminent dermatologists in England and abroad. I, of course, consented to do so, stating at the same time that I did not expect much good would result. I used a vacuum glass electrode connected to the top of the resonator, rubbing the electrode over the bald patches until a bright erythema was produced, which in this case did not take more than three or four minutes to each patch. Treatment in this manner was carried out three or four times a week for about three weeks and was then interrupted by the summer holidays. In September the patches were much smaller and fine hairs were seen to be growing in from the edges of each patch. Treatment was resumed, though not quite so frequently, for a little over two months. Hair was then growing vigorously all over the previously bald patches and by the end of the year the patient had a splendid head of hair which has maintained its good condition ever since.

From subsequent experience I have learned that the success obtained in this case was in all probability due to the ease with which hyperæmia was produced, and according as this is easy or difficult one can predict with a fair amount of certainty how far one is likely to be successful in any given case. In one case that I worked at vigorously for quite two months no good was done and the production of hyperæmia was most difficult, requiring severe sparking for a long time, and it faded away very rapidly afterwards.

In ordinary and premature alopecia, so long as the hair bulbs have not disappeared by atrophy and provided a good hyperæmia can be easily induced which persists for some hours after each application, much good of a lasting kind can be done and it is a method of treatment which ought to be in much more frequent use.

I am of the opinion that in the high-frequency spark we have a most valuable form of local stimulant which seems to have properties peculiarly its own and one the action of which is under perfect control in the hands of a person accustomed to its use. In this connexion I may say that I have employed it in an old-standing case of acne vulgaris and the rapidity with which the unsightly spots disappeared after some half-dozen applications was as surprising as it was satisfactory. The cure was, of course, not permanent, but with occasional applications the disease is easily kept under control and the method is found much more agreeable to the patient than those usually employed.

Another most valuable application of the high-frequency spark is in the treatment of port-wine marks. My first case was that of a young man who came to the London Hospital with a deep red patch of about the size of a penny on his right cheek. As I had been trying to do some good in similar cases by means of a fine galvano-cautery and by electrolysis, with indifferent results, I decided to try the high-frequency spark. For this purpose I used a metallic point electrode mounted on an insulated handle and connected with the top of the resonator. The point was held about one inch from the surface so that a hot white spark jumped across the intervening space. This was continued for several minutes until vesication was produced over the entire surface of the patch. There was no soreness afterwards worth mentioning and in about eight days the old epidermis peeled off, leaving a smooth surface, pink from the remains of inflammatory reaction, but otherwise quite like normal skin.

Another case was that of a young woman with several small stains scattered over the left side of the neck and lower jaw. Gentle treatment being desired I used a vacuum glass electrode, holding it about half an inch from the skin. This method is a more comfortable one but is not so efficient and takes a longer time. The result in this case was also quite successful.

In the last two cases the capillary vessels were confined to the superficial layers of the skin, and in all such cases this method of treatment offers little difficulty. Where the vessels extend more deeply vigorous treatment is necessary which may have to be repeated several times. I have now under treatment the most severe case I have attacked by this means. The nævus extends over the side of the neck, the cheek, the orbit, the side of the nose, and the upper lip. It is, or was, of a vivid red colour which was only partially removed by pressure. The case was one much too extensive to treat by any of the ordinary methods and I am not at all sure that the high-frequency treatment will be completely successful. The fact remains, however, that each application to any given part is followed by the removal of more or less of the redness, after the resulting inflammation has had time to subside. In those parts which have been treated twice—full time for complete subsidence of the inflammation being given after each—the redness is reduced by at least one-half. The patient is greatly encouraged and after going over these parts a third time it is believed that the discolouration will be so far reduced as no longer to constitute a serious disfigurement.

From such experience as I have had I have no hesitation in saying that port wine stains or marks, which at times constitute a very serious disfigurement, can be entirely removed by this method when they are only of moderate depth and extent, while the more severe cases can be at least very greatly improved.

A great advantage of the method is that the normal texture of the skin is quite unimpaired—there is nothing approaching a scar—thus differing from chemical agents and electrolysis. A further advantage is that it is under the most perfect control and no further reaction takes place than is desired.

Queen Anne-street, W.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Ligation of the Renal Vessels for the Cure of Persistent Urinary Renal Fistula, with One Successful Case.—A Case of Cervical Myelopathic Trichosis.

A MEETING of this society was held on May 28th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Major M. P. HOLT, R.A.M.C., read a paper on Ligation of the Renal Vessels for the Cure of Persistent Urinary Renal Fistula, with One Successful Case. He said that there were certain conditions of a patient with persistent urinary renal sinus when nephrectomy, in the absence of the usual contra-indications, was legitimate; but it was recognised by all authorities that in such patients nephrectomy, by reason of extensive matting of the kidney to certain surrounding structures, might be quite impossible or extremely hazardous, then the fistula must remain and the patient might have the prospect of accelerated death, or at best a miserable existence. Just four years ago a case of this kind came under Major Holt's care. Six months previously the patient had sustained a ruptured kidney and most extensive far reaching suppuration had occurred; during the next two years four separate attempts were made to perform nephrectomy, the difficulties were extreme, and on each occasion the operation had to be abandoned owing to furious hæmorrhage, so much so that further attempts were considered unjustifiable. Then it occurred to Major Holt that supposing the secretion of urine into the abscess to be the sole hindrance to healing, if permanent cessation of urine secretion on that side could be effected by ligature of all the renal vessels, then the abscess should rapidly and completely heal. No reference to any such procedure could be found in any available surgical literature, but the evidence of physiological laboratory work distinctly favoured the reasoning so far as concerned the secretion of urine. Accordingly, on June 13th, 1905, just two years and nine months after the original injury, during which time the patient had been slowly but surely losing ground, the renal vessels on that side were ligatured through the transperitoneal route. The operation was a complete success; within five days urine ceased to be present in the discharge and by the fifty-seventh day (August 9th) the sinus had completely healed. The patient has remained quite well since, now nearly two years. It was suggested that ligation of the renal vessels was preferable to any form of subcapsular piecemeal nephrectomy or morcellement, in that it presented none of the risks of the latter, and as effectually but more rapidly and more surely brought about a cure and that it deserved a further trial in suitable cases. The operation was very simple and was aseptic, in great contrast to nephrectomy under such conditions.—Mr. A. E. J. BARKER regretted that he had not known of this method previously, for had he done so he felt certain that he would have been able to benefit some patients whom he had failed to cure. He mentioned the case of a man who after an injury developed a hydronephrosis. An attempt to remove this was unsuccessful and subsequently the operation was attempted by another surgeon but the patient died under the operation. He thought this was a case in which the operation performed by Major Holt would in all probability have been successful.—Mr. STEPHEN PAGET pointed out that the ligature of the renal vessels left in the body an organ which though it had lost part of its function yet might still serve that which was concerned with internal secretion.

Sir WILLIAM R. GOWERS showed a patient with Cervical Myelopathic Trichosis. He said that the occasional occurrence in spina bifida occulta of a growth of hair across the lumbar region was pointed out by Virchow, Fischer, and von Recklinghausen. The facts had been described in an exhaustive lecture by Mr. J. Bland-Sutton.[1] The case which was now brought forward was one of similar trichosis in the cervical region, but it was unilateral and associated with unequivocal symptoms of cervical syringomyelia on the corresponding side. The patient was 41 years of age. The right arm and leg had always been a little weak, but the power in the arm began to lessen three years ago, and the weakness steadily increased, accompanied by rigidity and such excess of the wrist and other jerks that a clonus could be obtained in the flexors by pressing the fingers back. The weakness of the leg was slight, but it had always been a little smaller and less strong than the other and presented excessive knee-jerks and foot-clonus, the left being normal. Sensation on the leg and arm was perfectly normal and also on the trunk below the level of the shoulder. The spinal column seemed normal throughout, even in the cervical region. The lumbar region was free from hair; there was little on the skin in general. The cervical growth of hair occupied a triangle, of which the inner side was along the middle line of the spine from the sixth cervical to the third dorsal; opposite the first dorsal it extended nearly two inches from the spine. The hair was about an inch long and had existed all the patient's life. From the middle line a band of analgesia extended outwards from the fifth, sixth, and seventh spines to the shoulder, ceasing at the outer part of the clavicle. Sensibility to touch was unimpaired. Sensibility was normal to the left of the middle line. These facts pointed to a congenital arrest of development in the spinal cord (syringomyelia) in the cervical region. To this the state of the leg might be also due or to a slighter defect in the lumbar region. The recent development of the weakness in the arm might be reasonably ascribed to increased distension of the cavity or to a gliomatous growth of the adjacent tissue pressing on the pyramidal fibres of the arm. Another case was mentioned, that of a man, aged 26 years, who presented analgesia in the left leg only, with ulceration in the foot, which began in the toes when the patient was 12 years old, and had necessitated their amputation. The lumbar arches seemed intact, although opinions differed on this point, but he was born with an exuberant growth of hair in the lumbar region, bilateral, which was destroyed when he was eight months old by Mr. J. Warrington Haward. The case of cervical trichosis seemed unique in its position and association with evidence of syringomyelia. It seemed unique also in its unilateral character. The case presented a simpler problem than did the association with definite spina bifida. The opinion that the growth of hair was due to a vague process of irritation was without proof, and its explanation as a secondary trophic change was untenable, because it did not correspond in position to the trophic impairment due to the interference with the nerves, and because it was opposite in character, an epidermic nutritional excess, not a defect. The condition pointed to a disproportion between the inner and outer layers of the right neural ridge of the epiblast in the lower cervical region; before it united with its fellow, it split into two layers, the deeper to complete the neural tube for the spinal cord, and the superficial layer to form the epidermis over it. The inner part of the neural ridge thus formed the posterior part of the spinal cord on the side in which the defective development existed and relative excess of developmental energy in the outer layer and defect in the inner layer might be the cause of the condition. Its origin was thus taken back to the early weeks of embryonic life, even when the bones were intact. A notable feature of the cervical case was the fact that the growth of hair was of greatest vertical extent at the middle line corresponding to the edge of the neural ridge of the epiblast. Had the other side been also affected the area of trichosis would have presented a lozenge shape, which was strikingly present in some of the recorded cases of lumbar trichosis in spina bifida occulta.—The PRESIDENT said that he had removed the hair over the lumbar region because of its caudal-like appearance. He did not think there was any deformity of the lumbar vertebræ. There were loss of power in the muscles of the foot and loss of sensation. The ulceration of the toes arose from the fact that the boots were imperfectly fitted and this in association with his loss of sensation rendered the skin especially liable to destruction.—Mr. G. PERNET said that he had never seen a case of hypertrichosis which corresponded to the present case. He referred to some reported cases of hypertrichosis which had been associated with spinal disease. He thought that irritation might be the cause of hypertrichosis; this had been pointed out by various writers.—Dr. T. GRAINGER STEWART referred to the case of a man, aged 26 years, who was admitted to the National Hospital under the care of Dr. J. A. Ormerod. This man developed a spastic weakness of the right hand which gradually extended to the right leg and afterwards affected the left leg. There was dissociation of sensation and the seventh cervical spine was prominent. There was a scar over the back of the neck with one or two hairs. This was due to the removal of a "hairy bag of water" from the cervical region when a child. —Sir W. R. GOWERS replied.

MEDICAL SOCIETY OF LONDON.

Conversazione and Annual Oration.

THE annual conversazione of this society was held on May 27th, the Fellows and guests being received by Sir John Tweedy and Sir Edgcombe Venning, Vice-Presidents. Sir JOHN TWEEDY on taking the chair made feeling reference to the loss sustained by the death of Sir Joseph Fayrer, one of the past presidents of the society.

The annual oration was then delivered by Dr. G. A. GIBSON (Edinburgh), who chose as his subject the Cause of the Heart Beat. He commenced by reminding his hearers that the cause of the heart beat had not been investigated by Harvey, and that Albrecht von Haller was the first to speculate on the subject; but he only suggested that the cause lay in the heart itself. The discoveries of the nervous mechanism of the heart led to some more definite views and Volkmann formulated the conception that the cause lay in the action of the ganglia of the heart. These ideas were subject to some tidal currents of opinion and the ebb and flow of thought were seen in most of the standard works. Gaskell was the pioneer of the great army of workers who in the last quarter of a century had altered the current ideas. He showed that rhythmical pulsation decreased regularly from sinus to apex, and that the rhythmical power varied inversely as the distance from the sinus; that the power must lie in the muscle cells or nerve fibres, since some parts that could be made to beat had no ganglia; that the conduction of the contraction could only be seen when the "bridge" was intact; that the auriculo-ventricular ganglia of the frog could be removed without causing standstill; and that by nerve influence the rhythmicity, conductivity, excitability, contractility, and tonicity might be increased or lessened. In all this it was to be remembered that nervous tissues were present, and Gaskell frankly admitted as much. Carlson, in reviewing Gaskell's work, emphasised this fact and the further fact that no one had proved a direct action of the vagi on muscle. Engelmann followed Gaskell and in a long series of papers strove to prove myogenesis. He had advanced many analogies but no proof of the myogenetic hypothesis. The peristalsis of the ureter, in which he had forgotten the existence of nerves; the contraction of parts of the heart which had no ganglia, in which, however, there was a wonderful mesh of nerve fibres, which Carlson had shown to have more vitality than muscle cells; the beating of the heart after the removal of nervous interference by curare, which, it might be said, we did not yet know much of in regard to its influence on special cardiac nerves; and the arguments from embryology—admittedly the most powerful at the disposal of the myogenesists—all these were fully stated by Engelmann. Engelmann further claimed the law of Bowditch and the refractory period of Marey in favour of his views, ignoring the fact that they were as much in support of neurogenesis. The explanations of Engelmann and other myogenesists were sometimes so contradictory as to cancel each other. In connexion with this matter it might be said that the recent anatomical, physiological, and pathological studies of the sino auricular and auriculo-ventricular connexions (along with their extensions by means of Purkinje fibres) by Tawara and Keith, by Hering and Erlanger, by Stengel and by Dr. Gibson himself, had been claimed as proofs of myogenesis in forgetfulness of the presence of nerve cells and nerve fibres in these connexions. The recent beautiful work of Keith was fully detailed by Dr. Gibson as bearing on this aspect of the matter. Dr. Gibson further expressed the view that a block at the sinus—proved by Hering, Wenckebach, Ritchie, and himself—was clear evidence of neurogenesis, and that juvenile arhythmia and toxic cardiac disturbances were likewise powerful arguments in its favour. He showed how the evidence formerly advanced from the supposed myogenetic peristalsis of the intestine had had to be abandoned, since both on experimental and embryological grounds it had been discovered to be neurogenetic in origin. The researches of Romanes, Schäfer, and Carlson on the invertebrata were detailed, and it was shown that the conclusions to be drawn from them were all in favour of neurogenesis. It was freely admitted that as the heart of an invertebrate was not homologous with that of a vertebrate, such facts could only be used by way of analogy. The recent work of Yandell Henderson on the volume curve of the mammalian heart was described, from which that observer had been led to espouse neurogenesis. In Dr. Gibson's opinion the conclusions were distinctly in favour of those who held the neurogenetic view. The embryological facts could not be claimed by either side, as neither muscle nor nerve was present when the heart began to beat. The anatomical facts did not prove either hypothesis, for nerve and muscle were closely interwoven in the part which served to initiate the pulsation. Pathological evidence could be claimed by both schools of thought. Clinical observations, however, were distinctly in favour of the neurogenetic hypothesis. Beyond a doubt the curious structure recently described by Keith and Flack was that in which the pulsation took its origin, but the esoteric cause of the contraction was undoubtedly a rhythmic discharge from the nervous elements in the cardiac mechanism.

A vote of thanks to the orator was proposed by Sir EDGCOMBE VENNING, seconded by Sir LAUDER BRUNTON, and carried by acclamation.

The meeting then resolved itself into a conversazione.

CLINICAL SOCIETY OF LONDON.

Prolonged Intermittent Pyrexia.—Partial Heart Block.—Foreign Bodies in the Bronchi.—Annual Meeting.

A MEETING of this society was held on May 24th, Mr. H. H. CLUTTON, the President, being in the chair.

Dr. F. DE HAVILLAND HALL read the notes of two cases of Prolonged Pyrexia of an Intermittent Type. The first case was that of a man, aged 44 years, with pulmonary tuberculosis and enlarged glands; the second was that of a man, aged 21 years, with ulcerative endocarditis. After drawing attention to the late Dr. W. M. Ord's list of conditions giving rise to remitting or paroxysmal pyrexia, Dr. Hall pointed out that in practice cases of prolonged pyrexia were more commonly due to tuberculosis and malignant endocarditis than to any other condition. In arriving at a diagnosis family history might be of a certain assistance. On the other hand, a rheumatic family history should suggest the possibility of a rheumatic endocarditis. The past history of the patient would often yield valuable information—as, for instance, attacks of hæmoptysis. The comparative rarity of the association of valvular disease, and especially mitral stenosis, with pulmonary tuberculosis was insisted on. Stress was laid upon the importance of several examinations of the sputum, one or two negative results not being sufficient to exclude tuberculosis.—Dr. SYDNEY P. PHILLIPS remarked that it was the ate Dr. Charles Murchison who, in a classical lecture published in THE LANCET in 1879,[1] first drew attention to the numerous conditions which might give rise to intermitting pyrexia. The late Dr. Ord's contribution to the Medical Society of London was a later and not an improved edition of the same list of causes. Since Dr. Murchison's time a condition of arteritis had been shown by him (Dr. Phillips) to produce intermitting pyrexia; ulcerative colitis was another condition. The diagnosis of ulcerative endocarditis was undoubtedly very difficult and especially its differentiation from latent tuberculosis. Dr. Phillips took exception to the term "hectic pyrexia." The condition which used to be known as hectic fever, such as that which occurred with prolonged suppuration, was one in which the main symptoms were wasting and debility and the attendant pyrexia might be intermittent, remittent, or continued.—Dr. J. WALTER CARR, remarking on the second case, referred to the difficulty of diagnosis of ulcerative endocarditis, especially in cases where there was no previous history or evidence of cardiac disease and he referred to a case in illustration. The patient was an elderly man who presented some ulceration of the gums but no clue as to the existence of infective endocarditis.—Dr. J. G. GLOVER had seen some cases of rheumatic fever giving rise to intermittent pyrexia.—Dr. C. R. BOX referred to another cause of prolonged intermittent pyrexia—namely, chronic posterior basic meningitis. This condition gave rise to temperature charts just like those which had been exhibited.—Dr. HALL replied.

---

[1] THE LANCET, May 3rd, 1879, p. 617.

Dr. A. M. Gossage made a communication on Cases of Partial Heart Block. After pointing out that conductivity might be affected separately from the other functions of cardiac muscle, he explained that depression of conductivity showed itself chiefly in the muscle fibres that connect the auricles and ventricles. Depression of conductivity was illustrated by tracings showing a lengthening of the normal interval between the contractions of the auricles and those of the ventricles, and the dropping out of ventricular beats was shown when conductivity was further depressed—e.g., by digitalis or by the action of the vagus. Tracings were exhibited where there were three auricular beats to every two ventricular, two auricular to one ventricular, and three auricular to one ventricular. In the last two cases the patients exhibited the Stokes-Adams syndrome. The nervous attacks of this syndrome were shown to be preceded and accompanied by a cessation of ventricular contractions over a considerable period. Wenckebach had suggested the possibility of a block occurring between the veins and the auricles, and a tracing was shown where two successive ventricular beats had apparently been dropped, a circumstance which could be explained by a block between auricle and ventricle for the first beat and between vein and auricle for the second.

A communication on Foreign Bodies in the Bronchi, by Dr. F. W. Price, was taken as read so as to enable it to appear in the Transactions of the society.

The *ordinary meeting* was then followed by the final annual meeting of the society. The report of the council and the treasurer's statement of accounts were received and adopted. A special general meeting will be held on Friday, June 14th, to wind up the affairs of the society and to inaugurate the Clinical Section of the Royal Society of Medicine

---

Devon and Exeter Medico-Chirurgical Society.—*A meeting of this society was held on May 9th*, Mr. G. L. Thornton, Vice-President, being in the chair.—Mr. A. H. Hawkins exhibited a specimen removed post mortem in the hospital from a patient who died from uræmia, where only one kidney had been found, and this was very small and affected with advanced interstitial nephritis. The ureter on the opposite side was found but as far as could be discovered had a blind *termination.—Mr. C. E. W. Bell* reported the following cases, amongst others: 1. A case of Ovarian Tumour which showed marked pulsation which was much lessened on the patient *assuming the knee-elbow* position. It proved on operation to be a single, thin-walled ovarian cyst with no solid material at all. The patient made a good recovery. 2. A case of a married woman who had two children. She had had typhoid fever about six weeks before operation. On the right side was felt a swelling, tense and fluctuating, dull to percussion, slightly moveable, extending into the *pelvis*, and *plainly felt per vaginam* in Douglas's pouch. On operation it proved to be a suppurating cyst (ovarian?). This was incised and the walls were sutured to the peritoneum of incision and the patient recovered. 3. A man, aged 53 years, who in 1894 had a severe accident when cleaning an engine, falling into the cleaning pit. For six months previously to admission he had suffered from gastric symptoms, with attacks of pain and vomiting, and much loss of flesh. The vomit contained free hydrochloric acid and at times consisted of "coffee grounds." There was a distinct suspicion of thickening to be felt to the right and just above the umbilicus. A posterior gastro-enterostomy was performed. No tumour was discovered but the pylorus was *found to be much* flattened and bound down by adhesions. The patient rapidly improved and gained a stone in weight within a month of the operation. 4. A case of *Gangrene of the Leg* with marked diabetes. Amputation was performed through the thigh and the patient recovered. 5. A *case* of a boy who developed Intestinal Obstruction after *receiving* a blow in the abdomen from the handle of a bicycle. On opening the abdomen from 6 to 7 feet of collapsed bowel with adherent flakes of lymph were discovered, and a hole in the mesentery through which this loop *of gut* had slipped, so causing obstruction. The obstruction was removed and the wound was stitched up. The patient recovered. 6. A case of Chorion Epithelioma. The following was the history. The patient was 46 years of age. Two years ago she was under the care of Mr. H. Andrew in the Exeter Dispensary, with an abdominal swelling. This proved to be a *hydatidiform mole. After this* she suffered from considerable hæmorrhage and was admitted into the hospital. About a year ago she had a living child. She came under Mr. Andrew again *for* hæmorrhage one month before her admission into hospital, and *then she* had a uterine tumour of about the size of a cricket ball. It remained about the same size during the month under observation. A few days before admission a *small* nodule was noticed in the posterior vaginal wall. On admission the patient had severe hæmorrhage which spurted out of a small nodule or cyst in the *posterior* vaginal wall. This was scraped out and packed. Later, hæmorrhage took place *from* the bladder, and when this was examined under ether it was found to be involved by ulcerated growths. A nodule also appeared in the anterior wall of the vagina. *The hæmorrhage* continued and the patient died from exhaustion and anæmia. A microscopical examination of scrapings of the post-vaginal nodule *made by Dr. R. V. Solly proved* the case to be one of chorion epithelioma. A post-mortem examination was not permitted.—Dr. Solly showed microscopical specimens. He commented on the case of chorion epithelioma, referring to its pathology and the close relationship of the disease to hydatidiform mole. He further remarked on the connexion of the ovaries with these cases. According to Pick the lutein *cells of the* corpus luteum have an internal secretion, which so acts on the ovum as to cause it to become fixed to the endometrium and there develop, but *if there is an excess of* this secretion, owing to increase in the number of lutein cells, the ovum is over developed and a mole is formed. Cuthbert Lockyer had found that in many cases of chorion epithelioma the ovaries had many lutein cysts and where they were normal to the naked eye, on microscopical examination he had found an increase in lutein cells. Chorion epithelioma was most malignant, and besides having a local malignancy the cell elements were conveyed by the blood stream to the lungs, bones, and other organs. Chorion epithelioma should always be *borne in mind* where hæmorrhage continued after parturition or miscarriage, especially where there were an offensive discharge and elevated temperature, as the growth being so soft and friable was very *liable to be infected* secondarily, and so a sepsis and particularly a streptococcic infection was superadded. The only way to make a diagnosis was by microscopical *section of apparent blood clot.* Another most interesting fact about chorion epithelioma, which might arise from tubal fœtation as well as after miscarriage or parturition, was that tumours *identical* in structure were *found* in males, in *testicles* or intrathoracic tumours, or in the ovaries of women. These arose in connexion with cell seclusions or definite teratomata or teratoid tumours.

North of England Obstetrical and Gynæcological Society.—*A meeting of this society* was held at Leeds on May 10th, Dr. E. O. Croft (Leeds), the President, being in the chair.—The President showed a microscopical specimen from a case of Primary Carcinoma of the Urethra removed from a married woman, aged 37 years, who had complained of painful micturition with soreness and irritation for several months. The growth occupied *the posterior* lip of *the meatus* urinarius and extended three-quarters of an inch down the urethra, destroying the urethro-vaginal septum. Enlarged glands were present in both groins. Complete removal was impossible.—Dr. John B. Hellier (Leeds) exhibited a specimen of Tubal Mole removed from a nullipara, aged 30 years, who had been married four years.—The *President* introduced a discussion on the Treatment of Albuminuria and Eclampsia of Pregnancy. In speaking of pregnancy associated with pre-existing nephritis he urged that the pregnancy should not be interrupted until very thorough general treatment had been adopted, as many patients improved rapidly and completed the pregnancy *without* serious trouble. In considering albuminuria of pregnancy apart from eclampsia he urged the importance of complete recumbency, warmth, milk diet, and *eliminative measures*. The *pregnancy* need not be interrupted until indications were present that the disease was not under control. Spontaneous abortion from death of the fœtus *often rendered operative* interference unnecessary. In the event of the necessity for interference arising he advocated the gentlest method; rapid dilatation and evacuation under deep anæsthesia (especially ether) he considered to be bad practice. The treatment of the pre-eclamptic state required *more* vigorous attention to elimination, and rectal and gastric lavage followed by saline injections and hot packs proved useful. Pilocarpine might also have its use *in* this stage but it was dangerous during the eclamptic attack. Diaphoresis was more safely produced by the *hot* pack. The recognition of the pre-eclamptic stage gave *the* medical attendant time to adopt energetic measures. There was now no doubt that the pregnancy should be terminated by rupture of the membranes. In the absence of convulsions time might be given for dilatation to occur. Accelerative measures might be employed if necessary. The President then discussed the treatment of the eclamptic attack, including (1) the various methods directed towards the elimination of the poison or the control of the actual convulsions; and (2) the obstetric procedures for emptying the uterus. He approved of intravenous or subcutaneous saline transfusion as well as purgation by saline rectal injections and subsequent lavage. He had not found thyroid treatment effectual. For pyrexia he preferred the application of cold rather than the use of antipyretic drugs. He instanced two cases where the patient's temperature rose to 107° F. in a few hours. The operation of renal decortication required further evidence to justify its employment. He did not favour accouchement forcé, nor was Cæsarean section, in his opinion, ever necessary. He did not advocate mechanical dilators on the Bossi principle, preferring the trained and sensitive fingers of the obstetrician.—Dr. Hellier advocated all measures directed toward the elimination of the toxin. He used saline injection and transfusion. He was in favour of the interruption of pregnancy as removing the exciting cause of the toxæmia but did not believe in too rapid dilatation of the cervix and evacuation of the uterus.—The discussion was continued by Dr. David Lloyd Roberts (Manchester), Dr. William Walter (Manchester), and Dr. Alexander Stookes (Liverpool).

Reviews and Notices of Books.

The Practice of Gynæcology in Original Contributions by Eminent Authors. Edited by J. WESLEY BOVÉE, M.D., Professor of Gynæcology at the George Washington University, Washington, D.C. Illustrated with 382 engravings and 60 full-page illustrations. London: Henry Kimpton. 1906. Pp. 836. Price 31s. 6d. net.

IN order to secure breadth of view and a work which shall be of interest not only to the gynæcologist and the surgeon but also to the general practitioner this work has been written by seven gynæcologists under the editorship of one of them. As diseases of the rectum and the bladder are so intimately connected with the various affections of the pelvic organs they are also included. The arrangement of the book is founded upon pathology and bacteriology, so that a departure from the usual order has been made. As in most works which are written by several contributors there is considerable variation in the value of the different contributions.

After an opening chapter on the Examination of the Pelvic Contents by Dr. X. O. Werder follows a chapter on Developmental Anomalies of the Female Generative Organs by Dr. J. Wesley Bovée. The next two chapters on Menstruation and Displacements of the Uterus have been written by Dr. J. Riddle Goffe. The important subject of dysmenorrhœa is treated in very scanty fashion; no reference is to be found to it in the index and we are surprised to see the statement "that in many instances relief is to be afforded by removal of the ovaries and establishment of the menopause." Surely if any such drastic procedures are ever necessary or justifiable in the treatment of dysmenorrhœa the correct treatment would be to remove the uterus and not the ovaries. In the section on Displacements of the Uterus we are told that shortening the utero-sacral ligaments is the latest surgical device for relieving retro-displacements, and being the last in the process of evolution is therefore the best. With this deduction, founded as it is on an incorrect proposition, we disagree entirely. We are glad, however, to see that a few pages further on Pryor's method of causing obliteration of Douglas's pouch by packing with gauze is condemned.

The next four chapters, on Fæcal and Urinary Fistulæ, Lacerations of the Perineum, and Diseases and Injuries of the Vulva and Vagina, are of considerable value. The chapter on fæcal fistulæ deals with a subject which as a rule meets with very perfunctory treatment and is a most helpful one with a number of good illustrations. The difficult question of the operative treatment of ureteral fistulæ is fully gone into and the various operations are well described. In the 40 pages devoted to a consideration of lacerations of the perineum practically all the operations which can be performed for the relief of this condition are described, and this section, as is so often the case in American text-books, is especially full of detail. Dr. Noble does not on the whole approve of Tait's flap-splitting operation, perhaps the most frequently performed of all such plastic operations in this country. Dr. Noble's own operation and the apron operation of Warren, designed as they are to protect the wound from any contamination by the contents of the bowel, seem to us particularly ingenious and we should expect them to give excellent results. We are surprised to find that the necessity for an extensive removal of the whole of the vulva is not insisted on in the treatment of carcinoma of the vulva and nothing is said of the propriety of removing as far as possible the inguinal glands at the same time.

It is difficult to see on what system the various chapters are arranged; thus the chapter on Diseases of the Vulva is followed by one on Sterility, and this in its turn by a chapter on Diseases of the Rectum. The illustrations to this last chapter are of the crudest character and of very little value. Chapters XI. to XVII., on Inflammation of the Uterus, Lacerations of the Cervix, Inversion of the Uterus, and Benign and Malignant Tumours of that Organ, are written by Dr. G. Brown Miller. The section on endometritis contains a good account of this condition, the author being careful to separate from the inflammatory forms of that disease the cases in which the changes in the endometrium are in reality the result of chronic congestion only and are not inflammatory in origin at all. Under the heading of Subinvolution we are surprised to find the incorrect statements that immediately after delivery the fundus of the uterus is half way between the symphysis and the umbilicus and that on the tenth day the fundus is on the level of the upper margin of the symphysis pubis. In the treatment of inversion of the uterus the statement that the use of long-continued pressure on the inverted fundus by means of repositors or tampons is generally useless is hardly accurate, and we would certainly take exception to the statement that the best method of treating a chronically inverted uterus is by a modification of Küstner's operation. In the treatment of fibroid polypi we have never found it necessary to clamp or to tie the pedicle and it is certainly better to incise the tumour than to practise incision of the cervix as is recommended. The descriptions of the operations of abdominal hysterectomy and abdominal supravaginal amputation are not as good as the descriptions of the plastic operations on the vulva and vagina to which we have already referred. The very important question of the mode of spread of carcinoma of the cervix is, we think, inadequately considered in view of the important bearing which it has on the question of the choice of operation. The operation of vaginal hysterectomy is illustrated by a series of illustrations from Dudley's Diseases of Women, which are good, although they illustrate conditions never met with in the actual operation, but unfortunately those illustrating total abdominal hysterectomy by Kronig's method are poor. Two of the most interesting illustrations in the book are those on pages 460 and 461 of the simultaneous occurrence of sarcoma and carcinoma in the body of the uterus.

A special chapter by Dr. Goffe deals with the Vaginal Method of Operating; this of necessity leads to a good deal of repetition. Thus the operation of vaginal hysterectomy is fully described for the second time and so also are other vaginal operations. The technique of abdominal operations is considered by Dr. Werder.

Another instance of the want of method in arrangement is seen in Chapter XXIV., in which is given the anatomy of the Fallopian tubes and ovaries with the diseases of the *Fallopian tubes*, excluding infective processes and extra-uterine gestation which are discussed in a separate chapter further on. Some of the best chapters in the book are those by Dr. T. J. Watkins on Infections of the Fallopian Tubes and Ovaries, the etiology and pathology of the various conditions met with as the result of infective processes being well described, with many good illustrations. The concluding chapters are concerned with Extra-uterine Gestation and Diseases of the Kidney, Ureter, Urethra, and Bladder. The first is written by Dr. Werder and the remainder by the editor. The various affections of the ureter are very fully illustrated and the very excellent drawings from the Atlas of Tandler and Halban have been reproduced with great advantage to the text.

The whole work is, as we have said, unequal in its merits, for it has some most valuable chapters while others are far from attaining the same standard of merit. It contains, however, much information which is not as a rule to be found in the ordinary text-book of gynæcology and should therefore prove of value to practitioners and students.

The Muscles of the Eye. By LUCIEN HOWE, M.A., M.D., Professor of Ophthalmology, University of Buffalo, &c. In two volumes. Volume I., Anatomy and Physiology, including Instruments for Testing and Methods of Measurement. London and New York: G. P. Putnam's Sons. 1907. Pp. 455. Price, *separate volumes*, $4.25; together $7.50.

THE first part of this work is a description of the anatomy of the ocular muscles, their nerve-supply and blood vessels; a short chapter on comparative anatomy and embryology is added. The extraocular muscles are considered in great detail, stress being laid upon the importance of their "secondary" insertions. Whilst admitting the importance of these subsidiary expansions of the tendons it is difficult to assign their limits anatomically and still more so their individual physiological significance. After the elaborate description of the extrinsic muscles it is surprising to find the anatomy of the intrinsic muscles dismissed quite cursorily, though space is found for Iwanoff's antiquated diagrams of the ciliary muscle in emmetropia, myopia, and hypermetropia, diagrams which cannot now be considered to represent constant characteristics. The determination of the position of the lens by a modification of Javal's ophthalmometer and by Tscherning's ophthalmophacometer is discussed. According to the author there are many accessory muscles of accommodation, for they include most of the facial muscles. Much is made of the expansion of the occipito-frontalis fibres into the trapezius—"Later, reference will be made to this fact in connexion with headaches, pain in the occiput, or back of the neck." The ingenuity of the idea is perhaps its greatest merit.

The second part gives a good description of the physiology of the ocular muscles. It is clearly written and is well adapted to the student's needs. Scrupulous care has been shown in eliminating any reference to the bearings of the facts upon clinical conditions, for these will be dealt with in the succeeding volume. We are spared the wild generalisations which so often disfigure the writings of authors upon this subject. We hope that he will continue in the next volume to exhibit the same restraint which is characteristic of the present one. The physiology of the ocular muscles is treated in an orderly and philosophical sequence—one eye at rest, one eye in action but not necessarily in motion (accommodation), one eye in motion, both eyes at rest, both eyes in motion. Specially deserving of praise are the details of the actions of cycloplegics, mydriatics, and miotics, the author's measurements of ocular movements by photography, the descriptions of instruments and methods of measurement, and the relationship between convergence and accommodation. Stress is rightly laid upon the difference between false and true torsion, and the question is divested of many of the ambiguities which have accumulated around it.

There is a good bibliography and the volume concludes with portraits and biographical notes of Brewster, Helmholtz, Donders, Hering, Nagel, Le Conte, Hess, and Tscherning. The book is well printed, though considering the absence of half-tone illustrations it is unnecessarily heavy.

Manual of Anatomy, Systematic and Practical, including Embryology. By A. M. BUCHANAN, M.A., M.D., C.M. Glasg., F.F.P.S. Glasg., Professor of Anatomy in Anderson's College, Glasgow, &c. Vol. II., with 363 illustrations, mostly original and in colours. University Series. London: Baillière, Tindall, and Cox. 1907. Pp. xv.–950. Price 12*s.* 6*d.* net.

THE second volume of Dr. Buchanan's manual continues the regional arrangement adopted in the first and treats in order of the abdomen, thorax, head, and neck, central nervous system, and organs of special sense. Dissection guides to the various regions are appended to each section. The book is quite as comprehensive as many treatises of a more pretentious size. We find the descriptions readable and with a few exceptions they appear sufficient for all ordinary purposes. The arrangement of the book has rendered it necessary to consider the structure of the abdominal and pelvic viscera apart from their gross anatomy, consequently the full description of such viscera as the stomach, kidney, prostate, and so on, is only to be obtained by cross reference, which is a great drawback. For instance, the prostate is described on p. 798, but the description of its sheath, blood-supply, venous plexuses, and intimate structure is found 20 pages further on. The accounts of the development of the various organs are little more than brief summaries. The guides to dissection are of necessity compressed but they are something more than mere skeleton outlines and will subserve their purpose if the student is prepared for a good deal of cross reference. We again draw attention to the fact that they are printed in type which is uncomfortably small and since the book is obviously intended for use in the dissecting room as well as for general reading this objection is of considerable moment.

Seeing that the book is written for medical students, there are some points which call for criticism. Amongst other omissions we can find no mention of the auriculo-ventricular bundle of His, nor are the islands of Langerhans in the pancreas described. The downward extent of the spinal theca is not explicitly given, although it might be inferred from certain statements made. The lymphatics of the stomach, and indeed of several other organs, receive much less attention than their clinical importance demands. The illustrations, which are numerous, are well chosen but are not at all pretentious. The value of the description of the central nervous system is much enhanced by diagrams borrowed from the works of Poirier, Testut, and Charcot. An appendix contains the Basle nomenclature and a useful glossary of terms.

We congratulate Dr. Buchanan on the completion of his task and have no doubt that the book will find its sphere of usefulness.

Liverpool School of Tropical Medicine: Memoir XXI. London: Williams and Norgate. September, 1906. Pp. 118. Price 7*s.* 6*d.* net.

THE first part of this Memoir on African Tick Fever in Whites (caused by infection with the spirochæta duttoni) by Dr. A. Breinl and Dr. A. Kinghorn has already been dealt with at length in these pages.[1]

---

[1] THE LANCET, Jan. 5th, 1907, p. 23.

The following papers are also contained in the Memoir. 1. A Comparison between the Trypanosomes Present by Day and by Night in the Peripheral Blood of Cases of Human Trypanosomiasis, by the late Dr. J. Everett Dutton and Dr. John L. Todd. In this paper an account is given of observations made upon the blood of 20 cases of sleeping sickness at intervals of two hours extending over a period of 24 hours in ten of them and at intervals of four hours over a period of 72 hours in the other ten cases. As a control with regard to the possible effect of variations in temperature the blood of a heavily infected guinea-pig was examined after confining the animal in an incubator at different temperatures. No perceptible alteration was found in the number of parasites in blood taken from the ear. The conclusion drawn from the observation is that no marked qualitative or quantitative change, corresponding to day and night, occurred in the peripheral blood of the cases of human trypanosomiasis described in the paper. 2. The Lesions in the Lymphatic Glands in Human Trypanosomiasis, by Dr. R. Howard Mole. The author arrives at the conclusions that in the early stages of "human trypanosomiasis a remarkable and widespread increase of the germ centres in the lymphatic glands occurs, accompanied by a corresponding multiplication of the proper cells of the gland. As the disease progresses the germ centres become less prominent and not so evenly distributed in the gland. This change may be partly due to the formation of the sinus system, and partly to the growth of fibrous tissue and ultimate sclerosis of the gland. Finally, the germ centres are destroyed." There does not seem to be any conclusive evidence in the observations recorded in the paper that the changes in the lymphatic glands were really synchronous with the progress of the disease. In the very few cases dealt with the glands in some advanced cases did not seem to vary materially from those in early cases, while in other advanced cases they seemed to vary considerably. With the recent work which has been done upon leucocytes in view it is impossible to attach any great importance to the observations here recorded as they stand. No really valuable results could well be expected from material preserved in the ways described in the paper, though for these methods the author was not apparently responsible. 3. Concerning Certain Parasitic Protozoa observed in Africa, by the late Dr. Dutton, Dr. Todd, and Dr. E. N. Tobey. This paper is really a collection of preliminary notes. Some interesting observations upon malaria among the natives in the Gambia and Congo Free State are recorded. A peculiar form of onychia very probably due to a certain parasite similar to a spirochæta is described. Several trypanosomes found in different animals are also described in this paper. 4. Attempts to Cultivate Spirochæta duttoni, by Dr. Lewis A. Williams and Dr. R. Stenhouse Williams. The authors' experiments seem to show that while it is possible to keep the spirochætæ alive in defibrinated horse's blood for 28 days and in rabbit's for 25 there is no evidence that the parasites multiply when removed from the body of the host.

LIBRARY TABLE.

Practical Physiological Chemistry. By J. A. MILROY, M.D. Edin., and T. H. MILROY, M.D., B.Sc. Edin., F.R.S. Edin., Queen's College, Belfast. Second edition. London and Edinburgh: William Green and Sons. 1907. Pp. 201. Price 5*s*. net.—To judge of this work fairly we must remember that it is intended to serve as a guide to junior students attending a course of practical physiological chemistry of approximately three months' duration. It consists of four sections. Section I., Qualitative, deals with the usual subjects from organic substances, through secretions to urine—in all I.-XIV. chapters (pp. 1-111); Section II., Quantitative, deals with urine, blood, milk, gastric juice, and so on (pp. 125-169); Section III. is an Appendix on Reagents and Metrical Measures; and Section IV. sets forth Schemes for Detecting an Unknown Substance or Mixtures of Substances of Physiological Importance. We agree with the authors that they may have erred by introducing too much, for after all even a medical student's manipulative powers and memory are limited. The parts not directly suitable for junior students are placed within brackets and there are a goodly number of them. Unlike Professor Halliburton, the authors have adhered to the old proteid nomenclature and have not adopted the suggestions offered by the combined committee of the Chemical and Physiological Societies. The terms sclero-proteins for the familiar albuminoids, and protein hydrolysis for proteolysis have not been adopted. The work is carefully done and we feel sure that anyone following out such a course as is here laid down will have acquired a knowledge not of chemical physiology—for that is one of the most difficult of problems—but of the tests and reactions more especially useful to the medical student and of the quantitative methods that day by day increase in importance.

The Essentials of Histology, Descriptive and Practical, for the Use of Students. By E. A. SCHÄFER, LL.D. Aberd., Sc.D. Dub., F.R.S., Professor of Physiology in the University of Edinburgh. Seventh edition, revised and enlarged. With 553 illustrations, some of which are coloured. London: Longmans, Green, and Co. 1907. Pp. 507. Price 10*s*. 6*d*. net.—The reviewer's task in commenting on a work which has reached its seventh edition is always a light one and in this particular instance it is also a pleasant one, for Professor Schäfer's manual of histology is so well known and appreciated that criticism is superfluous. The present edition has been brought up to date and considerably enlarged, partly by additions to the text, especially to that descriptive of the structure of the central nervous system, and partly by the provision of new illustrations, many of which are coloured in order to give the reader a better idea of the appearance of the stained preparations. The opening chapter on the division of cells should prove of great value to the student as it contains a brief but concise *résumé* of the various forms of mitosis illustrated by excellent diagrams. Again, the chapter on the structure and development of bone is rendered clearer by the illustrations which are now coloured. As already stated, the chapter on the nervous system has been considerably amplified, many fresh illustrations are given, and all recent knowledge is incorporated in the text. The diagrams depicting the course of nerve fibres and tracts in the brain and cord and the probable relations of the cells and their axons are excellent and should prove of the greatest assistance to the student. The author is to be congratulated on the general excellence of this seventh edition of his well-known manual which we feel sure will attain even a greater measure of success than has been enjoyed by its predecessors.

LIVINGSTONE COLLEGE.—Commemoration Day at Livingstone College will be celebrated on June 5th, when the Right Honourable Sir John Kennaway, Bart., M.P., President of the Church Missionary Society, will preside. Short addresses will be given, after which the college rooms will be opened for inspection. The preservation of the health of missionaries and others in the tropics is a matter of great importance and it is for this purpose that the college was founded. Unfortunately, the deficiency of £216 with which the college accounts of the previous year closed has been increased during the last financial year to the sum of £522 and this will be further added to at the close of the present financial year unless liberal help is forthcoming. Cards of invitation to the Commemoration Day proceedings will be sent on application to the Principal, Livingstone College, Leyton, E.

Another instance of the want of method in arrangement is seen in Chapter XXIV., in which is given the anatomy of the Fallopian tubes and ovaries with the diseases of the Fallopian tubes, excluding infective processes and extra-uterine gestation which are discussed in a separate chapter further on. Some of the best chapters in the book are those by Dr. T. J. Watkins on Infections of the Fallopian Tubes and Ovaries, the etiology and pathology of the various conditions met with as the result of infective processes being well described, with many good illustrations. The concluding chapters are concerned with Extra-uterine Gestation and Diseases of the Kidney, Ureter, Urethra, and Bladder. The first is written by Dr. Werder and the remainder by the editor. The various affections of the ureter are very fully illustrated and the very excellent drawings from the Atlas of Tandler and Halban have been reproduced with great advantage to the text.

The whole work is, as we have said, unequal in its merits, for it has some most valuable chapters while others are far from attaining the same standard of merit. It contains, however, much information which is not as a rule to be found in the ordinary text-book of gynæcology and should therefore prove of value to practitioners and students.

The Muscles of the Eye. By LUCIEN HOWE, M.A., M.D., Professor of Ophthalmology, University of Buffalo, &c. In two volumes. Volume I., Anatomy and Physiology, including Instruments for Testing and Methods of Measurement. London and New York: G. P. Putnam's Sons. 1907. Pp. 455. Price, separate volumes, $4.25; together $7.50.

THE first part of this work is a description of the anatomy of the ocular muscles, their nerve-supply and blood vessels; a short chapter on comparative anatomy and embryology is added. The extraocular muscles are considered in great detail, stress being laid upon the importance of their "secondary" insertions. Whilst admitting the importance of these subsidiary expansions of the tendons it is difficult to assign their limits anatomically and still more so their individual physiological significance. After the elaborate description of the extrinsic muscles it is surprising to find the anatomy of the intrinsic muscles dismissed quite cursorily, though space is found for Iwanoff's antiquated diagrams of the ciliary muscle in emmetropia, myopia, and hypermetropia, diagrams which cannot now be considered to represent constant characteristics. The determination of the position of the lens by a modification of Javal's ophthalmometer and by Tscherning's ophthalmophacometer is discussed. According to the author there are many accessory muscles of accommodation, for they include most of the facial muscles. Much is made of the expansion of the occipito-frontalis fibres into the trapezius—"Later, reference will be made to this fact in connexion with headaches, pain in the occiput, or back of the neck." The ingenuity of the idea is perhaps its greatest merit.

The second part gives a good description of the physiology of the ocular muscles. It is clearly written and is well adapted to the student's needs. Scrupulous care has been shown in eliminating any reference to the bearings of the facts upon clinical conditions, for these will be dealt with in the succeeding volume. We are spared the wild generalisations which so often disfigure the writings of authors upon this subject. We hope that he will continue in the next volume to exhibit the same restraint which is characteristic of the present one. The physiology of the ocular muscles is treated in an orderly and philosophical sequence—one eye at rest, one eye in action but not necessarily in motion (accommodation), one eye in motion, both eyes at rest, both eyes in motion. Specially deserving of praise are the details of the actions of cycloplegics, mydriatics, and miotics, the author's measurements of ocular movements by photography, the descriptions of instruments and methods of measurement, and the relationship between convergence and accommodation. Stress is rightly laid upon the difference between false and true torsion, and the question is divested of many of the ambiguities which have accumulated around it.

There is a good bibliography and the volume concludes with portraits and biographical notes of Brewster, Helmholtz, Donders, Hering, Nagel, Le Conte, Hess, and Tscherning. The book is well printed, though considering the absence of half-tone illustrations it is unnecessarily heavy.

Manual of Anatomy, Systematic and Practical, including Embryology. By A. M. BUCHANAN, M.A., M.D., C.M. Glasg., F.F.P.S. Glasg., Professor of Anatomy in Anderson's College, Glasgow, &c. Vol. II., with 363 illustrations, mostly original and in colours. University Series. London: Baillière, Tindall, and Cox. 1907. Pp. xv.–950. Price 12*s.* 6*d.* net.

THE second volume of Dr. Buchanan's manual continues the regional arrangement adopted in the first and treats in order of the abdomen, thorax, head, and neck, central nervous system, and organs of special sense. Dissection guides to the various regions are appended to each section. The book is quite as comprehensive as many treatises of a more pretentious size. We find the descriptions readable and with a few exceptions they appear sufficient for all ordinary purposes. The arrangement of the book has rendered it necessary to consider the structure of the abdominal and pelvic viscera apart from their gross anatomy, consequently the full description of such viscera as the stomach, kidney, prostate, and so on, is only to be obtained by cross reference, which is a great drawback. For instance, the prostate is described on p. 798, but the description of its sheath, blood-supply, venous plexuses, and intimate structure is found 20 pages further on. The accounts of the development of the various organs are little more than brief summaries. The guides to dissection are of necessity compressed but they are something more than mere skeleton outlines and will subserve their purpose if the student is prepared for a good deal of cross reference. We again draw attention to the fact that they are printed in type which is uncomfortably small and since the book is obviously intended for use in the dissecting room as well as for general reading this objection is of considerable moment.

Seeing that the book is written for medical students, there are some points which call for criticism. Amongst other omissions we can find no mention of the auriculo-ventricular bundle of His, nor are the islands of Langerhans in the pancreas described. The downward extent of the spinal theca is not explicitly given, although it might be inferred from certain statements made. The lymphatics of the stomach, and indeed of several other organs, receive much less attention than their clinical importance demands. The illustrations, which are numerous, are well chosen but are not at all pretentious. The value of the description of the central nervous system is much enhanced by diagrams borrowed from the works of Poirier, Testut, and Charcot. An appendix contains the Basle nomenclature and a useful glossary of terms.

We congratulate Dr. Buchanan on the completion of his task and have no doubt that the book will find its sphere of usefulness.

Liverpool School of Tropical Medicine: Memoir XXI. London: Williams and Norgate. September, 1906. Pp. 118. Price 7*s.* 6*d.* net.

THE first part of this Memoir on African Tick Fever in Whites (caused by infection with the *spirochæta duttoni*) by Dr. A. Breinl and Dr. A. Kinghorn has already been dealt with at length in these pages.[1]

---

[1] THE LANCET, Jan. 5th, 1907, p. 28.

cases, the tuberculous process readily being grafted upon the simple disease. It may be thought premature that it should employ the term "fibroid phthisis" as the name for the non-tuberculous condition, since the word phthisis is still unfortunately in the minds of many persons connected with the idea of tuberculosis, the most chronic sclerosing forms of this infection being known as fibroid phthisis. Perhaps it might have been better to adopt the general term "pneumoconiosis" or "pneumonoconiosis" which has been coined to indicate fibrotic conditions due to inhalation of dust. We hope, in any case, before very long to see the use of "phthisis" as a synonym for pulmonary tuberculosis abandoned. With regard to the inclusion in the schedule of the malady in question, two difficulties arose: firstly, that of distinguishing the disease caused by the trade conditions from other affections of the lungs which attack all classes of the population; and secondly, the economic effects upon the workmen of adding this chronic malady, which may last for ten or 15 years without causing total incapacity, to the schedule of diseases for which the employer is liable to pay compensation. Regarding the first of these considerations, the committee holds that pneumoconiosis may be distinguished from tuberculosis and from bronchitis with emphysema by characteristic signs. From the former it is differentiated by the absence of fever and of emaciation; and from the latter by the tendency to retraction of the chest and by difficulty in inspiration rather than in expiration, as well as by the appearance of particles of grit in the sputum. This last phenomenon would, however, presumably be encountered in any patient suffering from simple bronchitis who was at the same time working in a dusty atmosphere. Probably if a group of well-marked cases of pneumoconiosis were compared with an equal number of typical cases of bronchitis and emphysema a skilled observer would be able to classify the majority without difficulty into the proper categories, but we are inclined to think that the proportion of doubtful and borderland cases would in actual practice be so large as to render an undesirable amount of litigation inevitable; while if such cases were brought into court a more than usual degree of divergence of scientific medical opinion might be anticipated. It would be interesting to know whether the x rays would be of any value in assisting in the diagnosis of pneumoconiosis, since the particles of dust, being of a mineral nature, should be opaque and should add considerably to the density of the shadow on the screen. The second point discussed by the committee in relation to this affection was the probable economic effect on the workers, since the employer would naturally wish to guard himself against the payment of compensation and would insist on careful medical examination of his workmen, declining to engage any who showed signs of the slightest pulmonary affection. Workmen who have at present the prospect of many years of active work would then be thrown out of employment on account of trivial ailments. It appears to be admitted that the effect of Employers' Liability Acts has already been to render it more difficult for elderly men to get or to keep employment; and in the case of a chronic ailment like pneumoconiosis the effect of adding it to the schedule would almost certainly be to diminish rather than to increase the general well-being of a large number of workers. Hence, the committee wisely decided to omit this ailment from the schedule of the Act. It is interesting to note that the attitudes of the various workmen's trade societies towards the proposal to schedule this disease differed one from another, possibly according to the degree of intelligence demanded by different occupations and the resulting diversity of powers to weigh immediate apparent gain against almost certain loss at a more distant date. The recommendations of the committee itself are founded on justice and common-sense, and so far as it is possible to judge in the absence of the evidence on which they were based we feel confident that they will commend themselves to all who have the welfare of the industrial population at heart.

New Vaccination Legislation.

IN our issue of May 11th we stated that Mr. JOHN BURNS had introduced into the House of Commons a Bill to substitute a statutory declaration for the certificate of conscientious objection required under Section (2) of the Vaccination Act of 1898. The Bill, which consisted of three clauses only, came up for second reading on May 24th, when Sir JOHN BATTY TUKE moved the rejection of the measure, Mr. CAVE, the Member for Kingston, seconding. Both speakers declined to believe that the Bill would effect a settlement of the vaccination question. Sir HENRY CRAIK and Sir FREDERICK BANBURY also opposed the Bill, the former saying that he considered the proposal of the President of the Local Government Board to be a concession to ignorance and prejudice. On a division Sir JOHN BATTY TUKE's amendment was rejected by a majority of 108 in a house of 122 and a motion for the second reading was agreed to without a division. Before the division was taken Mr. JOHN BURNS, in reply to various criticisms of the measure, reminded his hearers that he had indicated that certain alterations would be made in respect to vaccination and that the Bill under consideration gave effect to one of these promises. Another promise was that the cost of vaccination should be reduced. This promise he had been enabled to perform by a Local Government Board Order.

The Order in question, which now lies before us, is dated May 21st. It amends the Vaccination Order of Oct. 21st, 1898, and is founded upon the report of the Departmental Committee which was appointed in 1903 to inquire into the cost of vaccination. Shortly, it may be said that the main result of the Order is to reduce the fees payable to public vaccinators under certain conditions, but also in some ways to make their work less irksome. The Order will come into operation on Oct. 1st. As regards payments the minimum fee of 1*s.* mentioned in Article 3 (1) *a* of the Order of 1898 is not interfered with, but the other payments mentioned in the same article are altered as follows. We quote from the circular issued to guardians dealing with the Order:—

> The Order of 1898 requires that the contract shall provide for the payment to the public vaccinator of a minimum fee of 2*s.* 6*d.* in respect of every successful primary vaccination of any person other than a child or of any successful re-vaccination, where in either case the operation has been performed by him at his surgery or elsewhere than at the home of the person vaccinated. The new Order extends this requirement, so as to include any case of successful vaccination performed by the public vaccinator on a child whose age exceeds 12 months at his surgery or elsewhere than at the home of the child. The parent or person having the custody of the child must, however, have

Employers' Liability for Industrial Diseases.

THE recently issued report of the committee appointed by the Home Secretary to inquire into the subject of compensation for industrial diseases contains much interesting matter regarding a large number of different affections arising out of trade processes. Many of them are scarcely noticed in works on medicine and are practically known only to those whose practice lies among members of the trades specially affected. The Workmen's Compensation Act, 1906, contained a schedule of certain affections definitely arising from dangerous occupations for which the employer was made liable to compensate his workmen; these affections embraced poisoning by lead, arsenic, mercury, and phosphorus, and infection with anthrax and ankylostomiasis. The reference to the present committee was the selection of other trade diseases which might without injustice be added to this list. Two conditions practically govern the inclusion of any affection in the Act—namely, the length of time for which it renders the patient unable to follow his occupation, any period of illness less than one week falling outside the scope of the Act, and the possibility of recognising the disease as specifically caused by the workman's employment. Further, any affection which could be classed as an accident fell outside the scope of the committee's inquiry, being already covered by the Act. Here a difficulty at once arises, since it is not an easy matter to draw any hard and fast line between a disease or an injury which is due to an accident and one which cannot be so classified. For example, contact with poisonous gases may give rise to sudden unconsciousness and death, or it may, when prolonged, induce a chronic nervous affection. The criterion of an accident rightly adopted by the committee was its sudden and momentary character; and it was thus able to bring within the scope of the Act a considerable number of chronic intoxications incident to industrial occupations. In the present report the committee—the members of which were Mr. HERBERT SAMUEL, the Parliamentary Under Secretary of State for the Home Department (chairman); Professor T. CLIFFORD ALLBUTT of Cambridge; Mr. H. H. CUNYNGHAME, C.B., Assistant Under Secretary, Home Office; and Dr. T. M. LEGGE, medical inspector of factories—classifies the diseases with which it deals into the categories of general poisoning on the one hand and of local affections, involving the eye, skin, lungs, and other individual organs, on the other, and as the result of its labours it advises the addition of 18 new conditions to the schedule of the Workmen's Compensation Act.

Of the forms of general poisoning here dealt with some are already well recognised, such as the affections due to aniline poisoning and those caused by carbon bisulphide. It appears, however, that other benzene derivatives besides aniline may give rise to serious symptoms; for example, dinitrobenzol which is used in the manufacture of explosive agents. The toxic effects result from destruction of the red corpuscles of the blood in the first place, with signs of anæmia and cyanosis, but in more chronic cases the sensory and motor nerve endings are affected and muscular atrophy may ensue. Nitrous fumes may give rise to severe and even fatal poisoning in chemical works, and a dangerous gas, nickel carbonyl, is given off in the process of separating metallic nickel from its ore. An apparently novel disease is that resulting from the use of a poisonous wood from the plant Gonioma Komassi, or African boxwood, which is employed for making shuttles; headache, coryza, lacrymation, and asthmatic seizures occur, produced by the action of a special alkaloid of a very poisonous character, possibly resembling in its action the well-known arrow poison—curare. Among diseases of the skin the committee would schedule the ulceration resulting from contact with chromium compounds and the lesions which are produced by tarry products. Cancer of the scrotum as it occurs in chimney-sweeps is an allied condition which the committee also recommends for inclusion, though here it is possible to feel some doubt as to the correctness of its view, since it is difficult to be certain that careful personal cleanliness would not obviate the danger caused by soot and the employer should not be penalised for the workman's carelessness in such matters. Fortunately, the resulting epithelioma can be removed with reasonable prospect of permanent recovery. Not many diseases of the eyes seem to be directly traceable to injurious occupation, but miners' nystagmus, resulting from working in a constrained position with the eyes turned obliquely upwards, is scheduled, although the committee admits that considerable difficulty may arise in determining the exact amount of incapacity caused in individual instances, since the physical disability is not in all cases proportionate to the visible oscillation of the eyes. Cataract occurring in bottle-makers has been attributed to the action of the heat and light from the furnaces but the committee does not advise its inclusion in the list. Several local inflammatory conditions to which miners are liable are added to the schedule, among them præpatellar bursitis, so that it seems rather hard that the ordinary "housemaid's knee" occurring in domestic servants should be excluded when an almost exactly similar condition in miners is scheduled.

The most interesting section of the report is that dealing with the affections of the lungs which occur in workers in dusty occupations—grinders, potters, ganister miners, and so forth. Some controversy has existed in past times as to the nature of the resulting condition which is characterised by a gradually extending fibrosis of the lungs. This has been held, on the one hand, to be due to the direct irritation of inhaled particles of dust and, on the other hand, it has been regarded as a chronic tuberculous process, the entrance of the bacilli being facilitated by the action of the dust on the bronchial mucous membrane. The prevailing view, as set out by the committee, is that both accounts are true in different apparatus is furnished to every command. Lieutenant-Colonel LEISHMAN indicates also the method of preparing the vaccine, which is practically that of Sir A. E. WRIGHT modified in a few particulars; thus the temperature for killing the vaccine has been fixed at 55° C. instead of from 60° to 65° C. With regard to the objections to the process of inoculation the "local reaction" is now much milder, so that it is no longer necessary to inoculate in the flank, and hence the inoculated does not exhibit pain or stiffness in walking. The inoculation is now made in the arm or in the pectoral region. It is also pointed out that it is importan to carry out the second inoculation, as a higher degree of immunity is afforded by successive doses compared with that which is effected by a single one; a similar result has been noticed by the German army physicians in their Herrero campaign. The dosage of the vaccine has been fixed in the following quantity: one-half of a cubic centimetre of vaccine containing 500,000,000 of the bacteria is employed for the first inoculation, and double this quantity for the second; this amount has been ascertained to give the maximum quantity of protective substances with the minimum severity of reaction at present. With regard to the standardisation of the vaccine it has been found that no accurate measurement of its protective properties can be attained.

Major HARRISON in his paper reports on the results of certain experiments which have been undertaken in connexion with the antityphoid vaccine, such as those with reference to the various methods of killing the cultures by chloroform, heat, alcohol, and toluol, and those dealing with the antitropic substances produced by vaccines prepared in different ways. With reference to the duration of the immunity resulting from the inoculation, it has been ascertained that a bactericidal activity higher than normal and the presence of agglutinins in the serum of the men who have been inoculated last as long as six years, but it is not yet known whether the amount of protection remaining at this period suffices to ward off an attack. Lastly, Major HARRISON deals with the protective action of different vaccines against multiple lethal doses of a virulent typhoid culture. The third article on the subject is by Lieutenant LUXMOORE who contributes some very valuable data on the good effect of the inoculation as observed in an epidemic outbreak in the 17th Lancers at Meerut; this regiment left England in 1905 for India and within a few weeks after its arrival enteric fever broke out in it. The results obtained by the inoculation can really be held to constitute a *test case*, as they were checked by examinations of the blood and by necropsies. Lieutenant LUXMOORE details first the clinical effects of the inoculation, such as redness, pain, tenderness, and lymphangitis, with the general symptoms of a varying malaise, nausea, fever, and headache lasting for 36 hours as a rule but in one case for 48 hours. These local and general symptoms occurred again after the second inoculation but in a much less degree. The immediate source of the infection was not very clear but once started it was carried on doubtless by the agency of flies which were very prevalent until a solution of 2 per cent. crude carbolic acid was sub[illegible] earth in the latrines, when the flies diminished in number together with the cases of admission; by the dust, 25 per cent. of the cases showing marked bronchitis; and by the latrines and urinals. The proximity of the regiment to the native bazaar may also have had a large influence in the causation, while there was a failure of the rains in August and September, hence a large quantity of dust arose. With respect to the influence of the inoculation, Lieutenant LUXMOORE shows that of the 63 cases that occurred 61 were in men who were not inoculated, the remaining two being in men who would not submit to the second inoculation.

The perusal of these three articles can leave but one conclusion on the mind of the reader—namely, that inoculation for enteric fever is in every way as necessary for the protection of the health of the soldier in India as is vaccination against small-pox. Considering the large mortality that has up to the present time resulted amongst our men from enteric fever in the East we sincerely trust that this necessity may be recognised. It is satisfactory to learn that Lord KITCHENER is favourably impressed with the value of the treatment.

Annotations.

"*Ne quid nimis.*"

THE MEETING OF THE GENERAL MEDICAL COUNCIL.

ON Tuesday last, May 28th, the eighty-fifth session of the General Medical Council was opened, Dr. Donald MacAlister, the President, occupying the chair. In the President's address the programme of business was outlined and does not appear to contain as many urgent topics as have been under discussion on some recent occasions. Medical reciprocity with Nova Scotia was announced, certain changes in the formulas of poisonous drugs were foreshadowed in the next Pharmacopœia, a new print of the Standing Orders was made available for public use, and a financial surplus, which *though small* was satisfactory in the circumstances, was declared. The most interesting question broached by Dr. MacAlister referred to the position of members of the Council who are members of the British Medical Association if the Association should decide to act as complainant in any penal cases. The position is a difficult one and will perhaps give rise to debate in the Council.

CORONERS AND DEATH CERTIFICATES.

AT a meeting of the health committee of the Wrexham town council on May 15th the medical officer of health drew attention to the necessity for greater exactness in the certification of deaths, especially those *of infants. The infant* mortality is heavy in Wrexham and district and many children die without having had medical attendance. He regrets that in such cases the *coroner for the district* should issue certificates stating that the cause of death was "probably convulsions," and that when an inquest has been held "the evidence of an untrained and illiterate so-called midwife has been seriously taken as sufficient guarantee that the deceased died of convulsions." He mentioned the fact that "convulsions" was a symptom, not a disease, contrary to the popular notion. As the deadly disease "*spotted fever*" was present in the district and its main symptom was "convulsions" he thought it would be well if the committee would draw the attention of the coroner to the necessity of ascertaining by a post-mortem examination the real cause of death in those cases in which there was no

S. M. C. Medical College
1627

> requested that the child may be vaccinated elsewhere than at the home of the child and the public vaccinator must have satisfied himself that the child can be safely vaccinated having regard to Subsection (4) of Section 1 of the Vaccination Act, 1898.

The Order of 1898 requires that the contract shall provide for the payment to the public vaccinator of a minimum fee of *5s.* in respect of every successful vaccination or revaccination performed by him at the home of the person vaccinated. The new Order alters this requirement and directs that the contract shall provide in respect of such cases for the payment of an amount not less than the sums specified in the rules set out on p. 3 of the Order in question. The effect of these rules will be that where the district is situated wholly or partly in London, or in a borough or other urban district with a population according to the returns of the last census for the time being of not less than 50,000, the amount of the payment must in every case be not less than *2s. 6d.*, and that where the district is not so situated the amount must in every case be not less than *3s. 6d.* Elaborate instructions are laid down as to fees to be paid in cases where the public vaccinator vaccinates within a period of 24 hours two or more persons at one and the same home or any premises (other than the surgery of the public vaccinator) where these persons were together present at any time during the period. To quote again from the circular—

> In any such case the amount to be paid to the public vaccinator will be subject in respect of the first person vaccinated or revaccinated to the rules as to the minimum fees above referred to. But otherwise the amount to be paid in such cases must be mutually agreed upon by the guardians and the public vaccinator and approved by the Board, or in default of agreement determined by the Board.

The new Order extends the period within which a public vaccinator must visit a child after due notice given from two weeks to four, so as to give him an opportunity of arranging his visit for vaccination to any home at a time when he may have other professional work in the same neighbourhood. The arrangement of the various forms which the public vaccinator has to fill up has been altered so as to make them somewhat less laborious to deal with. We should add that although the minimal fees payable have been reduced, yet the circular points out to guardians that each case must be considered on its merits as regards the actual fee to be paid and arranged by contract; and the Board states that as regards districts which are only partly situated in London, or in a borough or urban district with a population of not less than 50,000, it is contemplated that a higher fee than the minimum will be fixed if the circumstances of the district in respect of area and population are such that a higher fee should properly be paid. We only hope that the Board's contemplative attitude may be justified, but we do not feel very sanguine on the point. Boards of guardians as a rule are unwilling to offer higher fees to medical men than the law compels them to offer.

◆

Antityphoid Inoculation in the Army.

Lieutenant-Colonel W. B. LEISHMAN, R.A.M.C., Major W. S. HARRISON, R.A.M.C., and Lieutenant E. J. H. LUXMOORE, R.A.M.C., have in the May number of the *Journal of the Royal Army Medical Corps* respectively contributed three papers on Antityphoid Inoculation in the Army which will well repay perusal. We have already briefly referred to these articles in our "Services" columns, but, as we stated at the time, they deserve more detailed consideration and we take this opportunity of returning to the subject. Lieutenant-Colonel LEISHMAN gives a *résumé* of "antityphoid inoculation" in his introductory contribution. This method, which was brought before the notice of the profession by Sir A. E. WRIGHT in 1897, was at first employed on a large scale in India and Egypt with most encouraging results, but after the Boer war it fell into abeyance temporarily, this being due to the fact that statistical evidence had been found hard to collect and that when collected it was only available for certain units. Such reasons for its abeyance, however, are difficult to understand, for the evidence that was obtained was practically entirely in its favour. During the Maidstone epidemic 84 nurses and attendants were inoculated and *not one was attacked* in contradistinction to 16 seizures amongst 120 nurses who were not inoculated, while the statistics which were obtained from the comparison of the inoculated and non-inoculated in the Boer war showed, as regards the Ladysmith, Princess Christian, Portland, Scottish National Red Cross, Kroonstadt, and Harrismith Hospitals, a much less incidence on the inoculated than on the non-inoculated. We have only to bear in mind these results to come to the conclusion that inoculation exercises a very marked beneficial effect. So far as we have been able to gather, there was only one adverse opinion with regard to the process—that, namely, of the late Dr. J. W. WASHBOURN of Guy's Hospital—and although this opinion must carry great weight from the personality of this distinguished physician still it is somewhat inexplicable when it is considered in connexion with the results which were elsewhere obtained in this war; at any rate, our German *confrères* have not wavered in their belief in the proceeding. Another and more valid reason was that the effects of a "negative phase" in the procedure might involve a possible danger due to the onset at first of a diminished resistance to infection. However, a committee was appointed to investigate the matter, of which Dr. S. H. C. MARTIN was President and Lieutenant-Colonel LEISHMAN was a member, the process having again been permitted after an interregnum of one and a half years, and this committee, which is still in existence, published in 1905 the results of the first portion of its work. This publication dealt with the quantitative tests of the substances that appear in the blood after inoculation and with the determination of the dose of vaccine which produces the greatest quantity of "protective substances" without undue local or general severity of reaction, and also without inducing a "negative phase" of resistance. Two inoculations with an interval of ten days were recommended, whilst it was urged that an officer of the Royal Army Medical Corps should be attached to each regiment going on foreign service. This officer was to undergo a special course of instruction at the Royal Army Medical Corps College and was to remain with the regiment for three years and to collect all information concerning the men who had been inoculated. Eight such officers have since been appointed. Lieutenant-Colonel LEISHMAN tells us that up to the present time 15,000 doses of the vaccine have been sent to India. A senior medical officer supervises the process of inoculation in each command and lectures to the men on its beneficial results, whilst a specially designed case of apparatus is furnished to every command. Lieutenant-Colonel LEISHMAN indicates also the method of preparing the vaccine, which is practically that of Sir A. E. WRIGHT modified in a few particulars; thus the temperature for killing the vaccine has been fixed at 55° C. instead of from 60° to 65° C. With regard to the objections to the process of inoculation the "local reaction" is now much milder, so that it is no longer necessary to inoculate in the flank, and hence the inoculated does not exhibit pain or stiffness in walking. The inoculation is now made in the arm or in the pectoral region. It is also pointed out that it is importan to carry out the second inoculation, as a higher degree of immunity is afforded by successive doses compared with that which is effected by a single one; a similar result has been noticed by the German army physicians in their Herrero campaign. The dosage of the vaccine has been fixed in the following quantity: one-half of a cubic centimetre of vaccine containing 500,000,000 of the bacteria is employed for the first inoculation, and double this quantity for the second; this amount has been ascertained to give the maximum quantity of protective substances with the minimum severity of reaction at present. With regard to the standardisation of the vaccine it has been found that no accurate measurement of its protective properties can be attained.

Major HARRISON in his paper reports on the results of certain experiments which have been undertaken in connexion with the antityphoid vaccine, such as those with reference to the various methods of killing the cultures by chloroform, heat, alcohol, and toluol, and those dealing with the antitropic substances produced by vaccines prepared in different ways. With reference to the duration of the immunity resulting from the inoculation, it has been ascertained that a bactericidal activity higher than normal and the presence of agglutinins in the serum of the men who have been inoculated last as long as six years, but it is not yet known whether the amount of protection remaining at this period suffices to ward off an attack. Lastly, Major HARRISON deals with the protective action of different vaccines against multiple lethal doses of a virulent typhoid culture. The third article on the subject is by Lieutenant LUXMOORE who contributes some very valuable data on the good effect of the inoculation as observed in an epidemic outbreak in the 17th Lancers at Meerut; this regiment left England in 1905 for India and within a few weeks after its arrival enteric fever broke out in it. The results obtained by the inoculation can really be held to constitute a test case, as they were checked by examinations of the blood and by necropsies. Lieutenant LUXMOORE details first the clinical effects of the inoculation, such as *redness*, pain, tenderness, and lymphangitis, with the general symptoms of a varying malaise, nausea, fever, and headache lasting for 36 hours *as a rule* but in one case for 48 hours. These local and general symptoms occurred again after the second inoculation but in a much less degree. The immediate source of the infection was not very clear but once started it was carried on doubtless by the agency of flies which were very prevalent until a solution of 2 per cent. crude carbolic acid was sub[illegible] in the latrines, when the flies diminished in number together with the cases of admission; by the dust, 25 per cent. of the cases showing marked bronchitis; and by the latrines and urinals. The proximity of the regiment to the native bazaar may also have had a large influence in the causation, while there was a failure of the rains in August and September, hence a large quantity of dust arose. With respect to the influence of the inoculation, Lieutenant LUXMOORE shows that of the 63 cases that occurred 61 were in men who were not inoculated, the remaining two being in men who would not submit to the second inoculation.

The perusal of these three articles can leave but one conclusion on the mind of the reader—namely, that inoculation for enteric fever is in every way as necessary for the protection of the health of the soldier in India as is vaccination against small-pox. Considering the large mortality that has up to the present time resulted amongst our men from enteric fever in the East we sincerely trust that this necessity may be recognised. It is satisfactory to learn that Lord KITCHENER is favourably impressed with the value of the treatment.

Annotations.

"*Ne quid nimis.*"

THE MEETING OF THE GENERAL MEDICAL COUNCIL.

ON Tuesday last, May 28th, the eighty-fifth session of the General Medical Council was opened, Dr. Donald MacAlister, the President, occupying the chair. In the President's address the programme of business was outlined and does not appear to contain as many urgent topics as have been under discussion on some recent occasions. Medical reciprocity with Nova Scotia was announced, certain changes in the formulas of poisonous drugs were foreshadowed in the next Pharmacopœia, a new print of the Standing Orders was made available for public use, and a financial surplus, which though small was satisfactory in the circumstances, was declared. The most interesting question broached by Dr. MacAlister referred to the position of members of the Council who are members of the British Medical Association if the Association should decide to act as complainant in any penal cases. The position is a difficult one and will perhaps give rise to debate in the Council.

CORONERS AND DEATH CERTIFICATES.

AT a meeting of the health committee of the Wrexham town council on May 15th the medical officer of health drew attention to the necessity for greater exactness in the certification of deaths, especially those of infants. The infant mortality is heavy in Wrexham and district and many children die without having had medical attendance. He regrets that in such cases the coroner for the district should issue certificates stating that the cause of death was "probably convulsions," and that when an inquest has been held "the evidence of an untrained and illiterate so-called midwife has been seriously taken as sufficient guarantee that the deceased died of convulsions." He mentioned the fact that "convulsions" was a symptom, not a disease, contrary to the popular notion. As the deadly disease "spotted fever" was present in the district and its main symptom was "convulsions" he thought it would be well if the committee would draw the attention of the coroner to the [illegible] of ascertaining by a post-mortem examination the real cause of death in medical man in attendance. He considered the issuing of certificates with such a vague and indefinite term as convulsions not only misleading but a positive danger to the public health. Our readers will be in general agreement with the view taken by the medical officer of health of Wrexham. In such cases as those indicated it seems not only mischievous but absurd for a legal coroner to give what he perhaps thinks is a plausible guess at the cause of death and to direct the jury to adopt it as their verdict. From a statement by the mayor it seems that this coroner "had criticised one of the leading medical men for not granting a certificate, although he had not seen the case before death"—surely, as the mayor remarked, "*a most improper thing to do.*" According to one of the councillors the coroner had given certificates in such cases without holding an inquest. It is only right to add that Mr. Kenrick, the East Denbighshire coroner, at an inquest held at Llangollen on May 21st, made the following statement as to the criticisms which he had received. "I think people who make these remarks ...... criticising my conduct, should, before they speak in public, make themselves thoroughly acquainted with the facts of the case. In no case since I have been appointed as coroner have I issued a notification dispensing with the necessity of an inquest unless I have been previously furnished with the certificate of a medical man stating, of his own knowledge, that the deceased died from natural causes and specifying the actual cause of death." This seems quite satisfactory so far as it goes, but it does not meet the statement which the Mayor of Wrexham is reported to have made that the coroner had criticised one of the leading medical men for not granting a certificate, although he had not seen the case before death.

WORKMEN AND DANGEROUS CONDUCT.

IN writing of the proposed inclusion of "potters' asthma" as an "accident" under the Workmen's Compensation Act in THE LANCET of May 25th, p. 1450, we suggested that the enforcement of the provision of proper safeguards by employers might in many cases be more just than to compel them to pay compensation in all cases of injury regardless of the workman's contribution to his own mishap. The proneness of the workman to neglect or to refuse the use of apparatus provided for his protection when he thinks that it interferes with his convenience is well known. The example given below is not one in which a sanitary precaution was disregarded, but it is one which shows strikingly the reckless manner in which men behave in employments to which they have become accustomed. At a recent inquest held by Dr. G. Danford Thomas at Paddington it was proved that the deceased, a man, aged 44 years, was employed by the Metropolitan Railway Company, having as one of his duties to oil the axle-boxes of the carriages. This he was, of course, expected to do when the carriage was stationary, and as a witness from the company reasonably said, it had never been imagined that anyone would do otherwise, so there were no specific orders on the subject but merely a general regulation forbidding dangerous conduct. The deceased had, however, laid himself flat on the gangway between two carriages of a train in motion, extending himself outside in order to oil an axle-box beneath him. It happened that a train travelling in the opposite direction had had a door accidentally left open or he might have performed his dangerous feat with impunity. As it was, the swinging door caught the man's head, fracturing his skull and killing him. When we find a workman of mature age behaving in this manner we are not surprised to learn that other members of his class are not easily made to acquiesce in protective measures against risks of poisoning or other injury which to us seem obvious but which to them may be shadowy and unreal, and we are prompted to some sympathy with employers who are compelled to adopt expensive safeguards and who (although these are adequate and proper) are also subjected to heavy pecuniary loss if their men obstinately refuse to help to protect themselves. Possibly time and education may bring workmen to adopt a line of conduct more intelligent and more reasonable, but the example of the railway man referred to is hardly an isolated instance of the difficulties with which employers have to contend.

THE HOME OFFICE REPORT OF EXPERIMENTS ON LIVING ANIMALS PERFORMED IN 1906.

A WHITE-BOOK has just been issued dealing with the experiments on living animals during 1906 and shows a satisfactory working of the present Act. The inspector is able to summarise the fitness of the experimenters for their work in these terms. The tables afford evidence that: "1. Licences and certificates have been granted and allowed only upon the recommendation of persons of high scientific standing. 2. The licensees are persons who, by their training and education, are fitted to undertake experimental work and to profit by it. 3. All experimental work has been conducted in suitable cases. The table dealing with the experiments is divided into two parts, containing details of those performed with and those without anæsthetics. In the first group for England and Scotland 1429 experiments have been performed under *licence* alone, in which the animal must be killed before the effects of the anæsthetic have passed off if the pain is likely to continue after this event or if any serious injury has been inflicted on it. 1357 experiments were performed under the various *certificates*, of which 159 were in illustration of lectures, the animals being killed before recovery from the anæsthetic; 281 were on cats and dogs and 917 on other animals for various physiological, pathological, and therapeutical experiments, in which the animal was allowed to live after recovery from the anæsthetic, without which proviso the experiments would have been rendered useless. These operations are required to be performed antiseptically and if suppuration ensues the animal must be destroyed. The report points out that "after the healing of wounds the animals are not necessarily or even generally in pain, since experiments involving the removal of important parts, including portions of the brain, may be performed without giving rise to pain after the recovery from the operation; and after a section of a part of the nervous system the resulting degenerative processes are painless." With regard to the second group of experiments we find the authoritative statement that "in no case has a cutting operation more severe than a superficial venesection been allowed to be performed without anæsthetics." This means to say that in the necessary interests of scientific medicine no pain has been inflicted by operation on any animal that is so severe as that of many surgical procedures which are daily endured by non-anæsthetised human beings. Under this group 63 experiments were done on horses, asses, or mules, 467 on dogs or cats, and 42,757 on smaller animals. Of these the vast majority consist of no more than the prick of a needle (such as thousands of human beings daily receive) for the purposes of inoculation or blood examination, and a few of them consist of feeding experiments. If an inoculation into a deep part involving a preliminary incision be necessary an anæsthetic is required. By the nature of the experiments, many of which are of a "standardising" nature, it often happens that no discomfort whatever results to the animal, but in the event of pain ensuing the animal must be killed under anæsthetics as soon as the main result of the experiments has been obtained. The increase of 7858 experiments over last year is more than accounted for by the increase of 8659 experiments performed on behalf of the Imperial Cancer

Research Fund; in this interest 21,082 experiments were altogether performed, of which 20,795 were inoculations into mice. It is encouraging to read that many of the experiments were performed on behalf of county councils, municipal corporations, and other official bodies, with a view to the preservation of the public health or for the diagnosis and treatment of disease. In Ireland 97 experiments were performed. The inspectors found that in all registered places the animals were well cared for and the licensees attentive to the requirements of the Act No irregularities were reported from Ireland and in England only four slight breaches the result of inadvertence or misunderstanding as to the scope of licences.

THE LATE SURGEON-GENERAL SIR JOHN KER INNES, K.C.B.

IN Florence (writes an Italian contributor) a movement has been started to commemorate this distinguished army surgeon whose later years were spent in promoting the welfare of the city. The animating spirit of many charities, medical and other, Sir John Ker Innes was also deeply and actively interested in the Anglo-Catholic Church of the Holy Trinity in the Via Lamarmora, the reconstruction of which owes much to him as chairman of the committee appointed *ad hoc*. It has been decided, therefore, that the contemplated memorial of him should take the form of a new inner porch to the church, with a suitable inscription, to recall the services, as numerous as they were valuable, conferred by him on the English-speaking community, resident and migratory, of the Tuscan capital. A subscription list towards the carrying out of this object has accordingly been opened and all who may be disposed to contribute are requested to communicate either with the Messrs. Haskard, Bankers, Florence, or with the chaplain, the Rev. A. A. Knollys, 70$^{\text{Bis}}$ Via Cavour.

A PLETHORA OF WINE IN THE SOUTH OF FRANCE.

A CURIOUS and perplexing situation has arisen in the wine-producing districts of South-Eastern France owing, it is said, to over-production. This has led to an acute economic distress which has occasioned rioting on the part of the great number of workpeople who are engaged in the industry there. Over-production does not, of course, necessarily imply that more wine than usual has been yielded or that the harvest has been unusually prolific. It most likely means in this case that the demand for wine in one district has diminished owing to the successful production of wine elsewhere. Competition, in short, has loaded a particular market and has led to a glut which has made the sale of the product no longer profitable. Immense quantities of wine are produced in Spain and in Italy, while France's rich colony, Algeria, exports to the mother country very large consignments of wine, whereas previously France sent wine into Algeria. It is alleged, however, by the organisers of the strike movement in the Midi that the systematic adulteration of wines has been largely responsible for the crisis, and an appeal is being made to the Government to make effective the laws applying to sophistication. It is most probable that the practice of *sucrage*, which under certain conditions is sanctioned by the French Government, has brought in its train widespread abuse. If weak grape-juice is artificially sugared it is obvious that a powerful wine can be produced which can be diluted with water and so a large bulk of so-called wine can be obtained. If this practice has led to the present crisis the victims of it have ample grounds for complaint and for taking up the strong attitude which they are reported to have done. The position is not calculated to affect the quality, quantity, or price of the excellent and genuine wines exported into this country from the Médoc. Even the cheaper kinds of claret, say at 12*s*. per dozen, are superior to the *vin ordinaire* which is consumed in France on a scale comparable with the drinking of beer in this country. It is, in fact, the every-day *vin ordinaire* that is chiefly concerned in this crisis, a cheap wine which owing to its "thin" qualities will not travel without losing its sound condition. It was a very risky concession for the French Government to make that when the vintage was poor the addition of sugar to grape juice might be permitted in order that alcoholic strength might be gained, and hence an increased bulk of apparently genuine wine produced. Dishonest dealing deserves disaster and the sooner the French Government organises a purifying crusade against the particular industry concerned, if the practice of sugaring the wine is at the bottom of the trouble, the better. We have every reason for believing that the supply of claret of both the cheap and elegant kinds from the Bordeaux districts to this country is still being maintained at that high standard of purity and excellence which was shown to be the case in the report of THE LANCET Commission on the subject 18 months ago.

PEMBROKE COLLEGE, OXFORD: A MEDICAL SCHOLARSHIP.

IN our issue of March 23rd we announced that Dr. C. Theodore Williams had founded a medical scholarship at Pembroke College, Oxford, his old College. The regulations concerning the scholarship are now before us and are as follows:—

1. The scholarship founded in Pembroke College in the University of Oxford by Dr. Charles Theodore Williams shall be entitled the Theodore Williams Medical Scholarship, and shall be administered as a scholarship of the College by the Master and Fellows.

2. It shall be adjudged after open competition, and natural science shall form the predominant part of the examination. Every candidate shall be required before admission to the examination to state in writing that it is his *bonâ fide* intention to proceed to the degree of B.M. and B.Ch. in the University of Oxford and to practise medicine or surgery.

3. The stipend of the scholar shall be £100 a year, so long as the income of the endowment shall suffice.

4. The scholarship shall be tenable for four years, provided that the holder's conduct and diligence be approved by the Master and Fellows, but in exceptional cases if the Master and Fellows shall so determine it may be held for a fifth year. The Master and Fellows may, if they think fit, excuse the scholar from residence during such fifth year.

5. If a scholar shall be guilty of any grave misconduct or shall be negligent of his studies, the Master and Fellows shall have power to suspend his scholarship or diminish his stipend, or deprive him of his scholarship. If at any time the Master and Fellows shall be satisfied that the scholar has abandoned his intention to proceed to the degrees of B.M. and B.Ch. they may deprive him of his scholarship. In case of deprivation the scholar may appeal to the Visitor, whose decision shall be final.

6 The Theodore Williams' scholar shall be required to pass all the examinations necessary for the degree of B.A., of which the Honour School of Natural Science shall be one.

7. The Theodore Williams' scholar shall enjoy the same privileges and be subject to the same duties as the other scholars of the College; and the by-laws affecting scholars shall be applicable to him except in so far as the Master and Fellows shall from time to time determine otherwise.

8. Not less than two months before holding any examination for the scholarship the College shall publish in the leading medical papers notice of the date of the examination and of its intention to proceed to an election.

9. Candidates must be unmarried and not more than 21 years of age at the time of election. They must send in satisfactory evidence of age and one or more testimonials of conduct covering the two years last preceding the time of their application.

This scholarship is, we believe, the first medical scholarship within the University. There are medical Fellowships, such as the Radcliffe Travelling Fellowship, and one of the Sheppard Fellowships at Pembroke College. There is also the Philip Walker studentship, but the holder of that must confine himself to pathology and the scholarship is not open to competition, neither is it restricted to members of the University. We are glad to see that Regulation 6 provides that the scholar must pass all the examinations for the degree of B.A., for although this regulation still holds good as regards the University there is no telling in these troublous times how soon an effort may be made to admit students to the examinations for the degree of B.M. who have not been through the Arts course. Pembroke College is to be congratulated on having so generous a son as Dr. Williams who is not forgetful of benefits received. The number of men who pass through the University content with the degree of B.A. without proceeding to the degree of M.A. is by no means creditable, and if they ignore their University still more do they ignore their College. To such, actions like that of Dr. Williams are both an example and a dignified reproach.

STUDIES IN EXPERIMENTAL ALCOHOLISM.

Dr. Reid Hunt, chief of the Division of Pharmacology of the United States Hygiene Laboratory, has recently concluded an extensive series of studies in experimental alcoholism.[1] Dr. Hunt undertook a series of experiments which he considers prove that profound modifications of certain physiological processes result, in a comparatively short space of time, from doses of alcohol so small that no indications of intoxication are observed. From a consideration of the known general effects of alcohol upon the metabolism Dr. Hunt was led to investigate the effect of alcohol in causing an increased oxidation of certain substances, particularly acetonitrile or methyl cyanide. This substance is very different from hydrocyanic acid, in its chemical and physiological properties, of which the latter are almost certainly due to the slow liberation of hydrocyanic acid in the body. Giacosa found thiocyanic acid in the urine after the administration of acetonitrile, whereas *in vitro* the oxidation of acetonitrile results in the formation of acetic acid. In the organism the hydrocyanic acid which is first formed subsequently unites with sulphur to form thiocyanic acid. A set of experiments was carried out to determine the effects upon the toxicity of acetonitrile of various substances that are supposed to influence physiological oxidations. One of the first substances studied in this connexion was alcohol. The experiments, which were made on mice, show that animals to which alcohol has been administered for some time acquire an increased susceptibility to acetonitrile. This occurs after the administration of amounts of alcohol far too small ever to cause indications of intoxication and from doses which almost certainly cause no anatomical lesions. This increased susceptibility is not due to a general lowering of resistance but is associated with a distinctly increased power of the body to break up the molecule of acetonitrile. The alcohol was administered by pouring it upon the food, usually oats, and it was slowly increased in strength from 5 to 50 per cent. The acetonitrile was injected subcutaneously in aqueous solution. In one experiment a mouse was treated with alcohol varying from 5 to 35 per cent. in strength over a period of about six weeks. After an interval of two months a dose of 0·23 milligramme of acetonitrile per gramme of body weight proved fatal in two hours. In a control experiment the mouse recovered after the administration of 0·42 milligramme per gramme. In this series of experiments it was found that the mice which had received alcohol died from about one-half the amount of acetonitrile that was required to kill mice which had not received alcohol. The experiments further show that there appears to be something special about the poisonous action of alcohol, inasmuch as certain other poisons—e.g., amyl alcohol and chloral hydrate—which cause a loss of weight and so might be considered as likely to lower the general resistance, do not have this effect. The formation of thiocyanic acid from acetonitrile appears to be a protective reaction on the part of the organism, the thiocyanic acid being less poisonous than the hydrocyanic acid formed from the nitrile. Experiments on guinea-pigs show that animals dosed with alcohol excrete 1·7 times as much thiocyanic acid after the administration of acetonitrile as do animals which have not been given alcohol. Dr. Hunt suggests that his experiments afford clear evidence that extremely moderate amounts of alcohol may cause distinct changes in certain physiological functions and that these changes may be injurious to the body in certain circumstances. The results also afford further evidence that in some respects the action of alcohol as a food is different from that of carbohydrates and also that in all probability certain physiological properties in moderate drinkers are distinctly different from those in abstainers. These experiments are of extreme interest because of the clear demonstration which has been made in recent years that alcohol is oxidised in the body and may replace fats and carbohydrates and to a certain extent the proteids of an ordinary diet. As a result the view that alcohol in moderate amounts should be regarded as a food is almost universally accepted by physiologists. The drift of opinion is certainly towards the view that it is in all respects strictly analogous to sugar and fats, provided always that the amount used does not exceed that which can be easily oxidised by the body. Under these premisses it would be expected that alcohol in a diet would have the same effect upon an animal's susceptibility to acetonitrile as has, for example, dextrose. But this is by no means the case. Mice fed upon oats and dextrose show a very distinct resistance to acetonitrile, often recovering from two or even three times the dose which is fatal to controls. Dr. Hunt considers that while these facts are not sufficient to justify the conclusion that in many cases alcohol has not a true food value, yet they are sufficient to indicate caution in applying to practical dietaries without further investigation the brilliant and very exact results of Chittenden as to the proteid-sparing power of alcohol.

THE SALE OF PROPRIETARY MEDICINES ABROAD.

IN an interesting paper on secret remedies, which appeared in a recent number of the *Pharmaceutical Journal*, Mr. J. Cofman has given some particulars of the restrictions that are placed upon the sale of proprietary medicines abroad. In France the law of the eleventh year of Germinal prohibits the sale of any compound medicine, the formula of which is not published in the Codex Medicamentarius, or in the *Bulletin de l'Académie de Médecine*, or by the Government. This law does not apply to the written prescriptions of qualified medical men. The publication of advertisements recommending medicines is also prohibited. This law does not appear to be enforced rigidly, as about 4000 proprietary remedies are advertised and sold throughout the whole of France. In Germany different States have different laws against secret remedies but a general law is now in contemplation. In some States of Prussia, Würtemberg, and Bavaria the public authorities have warned the people against quackery with excellent results. The advertising of secret remedies is prohibited in Brunswick and in other States, even when the formula is published. In Austria a new preparation may not be sold without a medical prescription until its therapeutic action has been clinically tested and approved of by the medical authorities. Pharmaceutical specialities may be made only by pharmacists in business from drugs or chemicals admitted in medicine and they must possess some element of novelty or show some improvement as regards their physical properties. If a preparation is sold only in the maker's own pharmacy the exact formula must be entered in a special register which is kept for inspection by medical men. If the preparation is to be advertised and sold in other pharmacies special authorisation must be obtained. The price is calculated from the wholesale cost of the ingredients, working expenses being included according to a tariff. Advertising expenses and discount to retailers are not allowed to increase the cost of the article. The Customs houses and postal authorities refuse to deliver medicines entering Austria from abroad to anyone but a pharmacist. The advertising or sale of quack remedies is not allowed in Austria. In his letter at p. 1528 our Vienna correspondent also deals with the matter.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: ANNUAL ELECTION TO THE COUNCIL.

A MEETING of Fellows of the Royal College of Surgeons of England will be held at the College on Thursday, July 4th, for the election of four Fellows into the Council of the College in the vacancies occasioned by the retirement in rotation of Sir John Tweedy, Mr. Herbert William Page, Mr. Charles William Mansell Moullin, and Mr. Frederic Samuel Eve. Sir John Tweedy's period of office expired three years ago, but, being President, he was entitled to retain his seat on the Council until he vacated the President's chair. Mr. Moullin was elected to the Council in the year 1902 as substitute for the late Sir William MacCormac, and Mr. Eve was elected in the year 1904 as substitute for the late Mr. T. R. Jessop. The terms of office of these two deceased gentlemen as members of the Council would have expired this year. Mr. Page was elected in the year 1899, and thus completes the full period of office for a member of Council—eight years. The poll will be open for personal voting between the hours of three and five in the afternoon. A voting paper will, however, be sent to each Fellow who may desire to vote by post and whose address in the United Kingdom is registered at the College on June 21st, and Fellows will not be required to apply for voting papers.

THE WINTER ON THE SWISS MOUNTAINS.

THE following figures represent the mean temperature in the shade at 7.30 A.M. and at 1.30 P.M. mid-European time, the aggregate number of hours of bright sunshine, and the total fall of snow in inches of water during the four months December, 1906, to March, 1907.

—	—	Temperature.		Sunshine. No. of hours.	Rainfall.	
		7.30 A.M.	1.30 P.M.		Days with snow.*	Total fall.

	March	19	†	†	8	1·7

* A day when the snowfall gave a measurement of at least 0·04 inch when melted.

† No observations available.

The chief feature of the temperature is perhaps the little difference between the morning and afternoon readings at the two most elevated stations—Säntis and St. Gothard—when compared with the corresponding difference at Davos, which is on the lower level of 1560 metres above the sea. But although the frost was more intense at the highest position the duration of sunshine was also greater, and this must have been more than a counter-balancing advantage. All the stations occasionally experienced morning temperatures below zero, but they were more common at Säntis and St. Gothard than elsewhere, and the lowest reading at 7.30 A.M. was no lower than 8° below zero, showing just 40° of frost. At Davos the thermometer was above the freezing point at 1.30 P.M. on 27 days, of which 16 were during March, three in December, and only two in January. Readings above 35° were extremely rare, and the highest point touched by the thermometer was 41° at Davos at the end of March. At the higher observing stations of St. Gothard and Säntis the freezing point was exceeded on only two or three afternoons, all of which were in March. The atmosphere was, of course, very dry except during foggy spells but the actual figures of relative humidity are lacking. The number of days on which snow was experienced was small at Säntis and St. Gothard, as was also the actual quantity.

MEAT EXTRACT AND YEAST EXTRACT.

WE have intentionally refrained, pending some inquiries as to the reasons underlying the extraordinarily conflicting evidence given by analytical experts, from making any comment on an important case recently heard at Marylebone police-court, in which the question at issue was whether a certain extract contained extract of meat or extract of yeast, or both. The case, in short, for the prosecution was that a certain preparation had been sold to the public as a meat extract, whereas, in fact, it was essentially a vegetable or yeast extract containing on an average only 8 per cent. of extract of meat and a proportion of flavouring to give it the appearance and smell of a meat extract. The case for the defence was that it did actually contain 18 per cent. of meat extract and that when the descriptions of the article were liberally interpreted they would be found to be scientifically correct. The evidence for the prosecution was based upon the amount of creatinine found in the extract by a process of analysis adopted by Mr. Otto Hehner. This witness stated that meat extract contains about 11 per cent. of creatine *plus* creatinine and in all the extracts of meat which he had examined he found that this amount was practically constant. This invariability of the amount of creatine in extract of meat was denied but at any rate a quite definite figure is obtained for beef—namely, 0·41 per cent., and as the yield of extract from beef is about $\frac{1}{25}$th to $\frac{1}{30}$th of its weight it follows that the creatine and creatinine in the extract should approximate to from 10·25 to 12·30 per cent., figures which are absolutely in accordance with Mr. Hehner's results. Dr. B. Dyer, Mr. A. C. Chapman, and Mr. Gordon Salamon, analytical experts for the defence, contended that the method adopted by Mr. Hehner was new, untrustworthy, and worthless, Mr. Salamon adding that he was amazed at such an able and responsible authority as was Mr. Hehner bringing forward such a test. The magistrate, Mr. Paul Taylor, also took this view and accepted this evidence. He dismissed the summons, with £200 costs. By the courtesy of Mr. Hehner we have obtained from him the particulars of the method which he adopted for the determination of creatinine, on the results of which he based his evidence. It is hardly necessary now for us to say that we believe his results and the opinion founded on them to be absolutely correct, for Dr. Dyer, Mr. Chapman, and Mr. Salamon have since acknowledged "the superior accuracy of Mr. Hehner's numbers." They, however, maintain that the proportion of creatine and creatinine in the manufactured product entirely accords with the sworn testimony of the manufacturers as to the quantity of meat extract used—viz., 18 per cent.—in whichever way the test is carried out, and the difference between them, they assert, did not after all affect the question at issue. It seems strange that the time of the court should have been so largely occupied with the hearing of analytical evidence if this evidence did not affect the question at issue and if it did not as a matter of fact guide the magistrate to the decision which he gave. However, the fact is that the test failed in the hands of the expert witnesses for the defence because they omitted to observe certain precautions in regard to carrying out the test the result of which was to give them figures far below the truth. It may be added that the differentiation of meat extract from yeast extract is based on the fact that the former contains creatine *plus* creatinine, while the latter contains, practically speaking, neither of these bodies. Creatinine yields when heated with alkaline picrate a blood-red colouration due to the formation of creatinine picrate. Creatine does not react in this way until it is first heated with dilute hydrochloric acid which converts it into creatinine. The colouration can be imitated by operating on a definite quantity of a standard solution of pure creatinine and so the amount in a given preparation may be estimated. The main point to be observed in this method is to insure that the picric acid is present in amount sufficient, or more than sufficient, to combine with all the creatinine present. Otherwise the results will be irregular and below the real figure. We consider that the analytical evidence in this case was of the utmost importance and it was most unfortunate that the mistake in analytical procedure was made, even if it was satisfactorily established that the preparation in question contained meat extract. As long as it is described honestly there is, of course, no objection to yeast extract being sold for dietetic purposes. It resembles meat extract in appearance, colour, and taste, and possesses similar dietetic properties, but it is not meat extract any more than margarine is butter. The occurrence of questions of this kind emphasises the need for the existence of a court of reference of experts or of a tribunal qualified to try highly technical cases.

GORILLAS AND PRIMITIVE MAN.

IN his interesting lectures on the Prehistoric Inhabitants of Britain, recently delivered at the Royal College of Surgeons of England, Mr. W. Wright exhibited the skull of a gorilla and contrasted it with the crania of primitive man. It is now nearly 60 years since a previous Hunterian professor, the famous Richard Owen, insisted on the same contrast. Owen's, of course, was the anti-Darwinian point of view, whereas Mr. Wright showed diagrammatically that crania tend to develop from a lower or ape-like form to a higher. When in 1859 Owen added an appendix "on the gorilla" to his reprint of lectures on the Classification and Geographical Distribution of the Mammalia, the animal was still a novelty in England. The species may indeed be said to have been re-discovered by Dr. Savage, a missionary in the Gaboon, who in 1847 sent sketches of it to Owen, but no live specimen of the gorilla seems to have been seen in England till after the publication of Owen's lectures, when one was for a time quartered at the Crystal Palace in 1859. The creature became the centre of myths. The public, including the great Owen himself, were inclined to believe the species not far removed from prehistoric man. Owen quotes romantic negro beliefs in which he is inclined to place credence as "in accordance with the ascertained structure and powers of the animal." The gorilla, according to Owen, makes a sleeping-place like a hammock. He cracks nuts with a stone and is said to walk half erect with the help of a club. Native beliefs, which Owen quotes without adopting, were that the animal built huts and roughly buried its dead. "All the terms of the aborigines in respect to the gorilla imply their opinion of his close kinship to themselves. But they have a low opinion of his intelligence." Thu Owen unconsciously played into the hands of those wh at that time were inclined to assert the descent of man from a gorilla-like type. In 1861 du Chaillu published hi remarkable book of travel in Equatorial Africa and described his experiences of the gorillas, all the pretty myths concerning which he ruthlessly exploded. The creature he shows to be just a great ape without human habits of any kind. Thus the theory of evolution holds man and the apes to have an ancestry in common, yet scarcely any arguments can be brought to support this belie from a consideration of the habits, as opposed to the anatomy, of the great apes.

THE WESTMINSTER CITY COUNCIL AND THE STREETS.

WE have upon previous occasions been at issue with the Westminster city council as to its management of the streets in regard to sanding them in slippery weather and also as regards the removal of snow. It is pleasant, therefore, to be able to give the council credit for its forethought as expressed in a circular just sent out. This circular informs all whom it may concern that certain streets within the boundaries of the City of Westminster will be repaved on or about certain dates. The circular further states:—

> The contracts provide for the work to be completed with all dispatch and with as little inconvenience as possible to those occupying premises along the street. The gas, water, electricity, telephone, telegraph, lighting, hydraulic power, and other trenching companies have been notified in order that they may carry out any alterations and repairs to their mains and services immediately prior to or during the execution of the proposed works, with the view of obviating interference with the paving by them in the near future. The police authorities have also been informed of the intended works, so that they may make such arrangements as are necessary for the direction and control of the street traffic during the time the street works are in the hands of the contractor.

With regard to the question of "all dispatch," we wonder whether the contract provides for the working of a night shift in the non-residential districts concerned. If work were carried on continuously day and night in, for instance, that portion of Charing Cross which is affected the inconvenience and the delay to the traffic would be reduced by one-half. We trust that the "trenching companies" will avail themselves of the opportunity afforded to them and thus also earn our congratulations. Certainly the Westminster council deserves every credit for making so gallant an effort to minimise the nuisance which invariably follows the repaving of a road.

HEMIPLEGIA WITHOUT LESION OF THE PYRAMIDAL TRACT.

THE association of hemiplegia of organic type with a lesion of the pyramidal system in some part of its course is one of the most definitely established facts in neuropathology, and according to Probst no case of organic hemiplegic paralysis without such a lesion is on record. A case observed by Dr. Spielmayer[1] of Freiburg and described by him at the meeting of the neurologists and alienists of South-West Germany held at Baden-Baden is therefore of very great interest in this connexion. Clinically the case appeared to be one of genuine epilepsy with characteristic convulsions. The patient, who was originally an intelligent woman, gradually became weak-minded and stupid. There were not at any time Jacksonian fits or any post-epileptic paralyses until two years before death (which occurred at the age of 41 years) when after an attack of status epilepticus a left-sided hemiplegia developed. This showed the typical characters of a cerebral lesion and followed the usual course of that condition. It was therefore supposed that a hæmorrhage into the internal capsule had occurred. At the necropsy no trace of such a lesion was found, nor did a most careful microscopical examination bring to light any lesion of the fibres of the pyramidal system in the pons, medulla, or spinal cord which presented identical characters on the two sides. It was found, however, that the whole of the right hemisphere was atrophic, especially so in the neighbourhood of the fissure of Rolando. Specimens prepared from the ascending frontal convolution and stained by Nissl's method and by Weigert's neuroglia stain demonstrated the replacement of the cellular layers by neuroglia with the exception of the layers of giant pyramidal and large pyramidal cells which in number, arrangement, and structure were identical with those of the sound side. It is well known that these cells are the trophic cells from the pyramidal fibres and the absence of any pyramidal lesion was therefore explained. From the examination of the cortex cerebri it would therefore appear that the hemiplegia in this case owed its origin to a lesion of the sensori-motor path beyond the upper motor neuron. It is interesting in this connexion to recall the experiment of Mott and Sherrington who showed that after section of all the posterior roots entering into the formation of the brachial plexus in monkeys the arm was paralysed, although the pyramidal tract was intact and was excitable to subsequent stimulation. It would have been of interest to know whether in Dr. Spielmayer's case the paralysed side was convulsed in fits occurring subsequently to the hemiplegia. The case is noteworthy, not only on account of its rarity but also because of the care with which it was worked out and the suggestive nature of the conclusions arrived at.

INTERNATIONAL CONGRESS ON PSYCHIATRY, NEUROLOGY, PSYCHOLOGY, AND THE CARE OF THE INSANE.

AS already mentioned in THE LANCET of March 2nd, p. 605, an International Congress on Psychiatry, Neurology, Psychology, and the Care of the Insane will be held in Amsterdam from Sept. 2nd to 7th. Membership of the Congress is open to all who may be interested in the above subjects. The official languages are English, French, and German. Members pay a subscription of 10 gulden or 16*s.* 8*d.*, and ladies accompanying them a subscription of 5 gulden or 8*s.* 4*d.* A programme has now been issued giving full details of the arrangements. The work of the Congress will be conducted in three sections and there will be an exhibition of objects of interest. The first section will deal with Psychiatry and Neurology. The principal official subjects of discussion will be Theories of Hysteria, Psychoses Connected with Alcoholism, Diagnosis of Various Forms of Dementia, and the Cortical Localisation of Certain Functions. The second section will deal with Psychology and Psycho-physics. The principal subjects will be the Psychology of Puberty, the Difference Between Perception and Idea, and the Previous History of the Insane. The third section will deal with the Care of the Insane. The principal subjects will be the Management and Control of Asylums, Supervision of the Care of the Insane by the State, Instruction and Duties of the Attendants, Boarding-out, Alcoholism, and the Education of Backward Children. National committees are appointed in each of the countries represented at the Congress. The committee for Great Britain and Ireland consists of 17 members, Dr. Robert Jones of the London County Asylum, Claybury, Essex, being the president. The Congress will be opened on Sept. 2nd at 2 P.M. in the presence of Queen Wilhelmina, after which there will be a reception of the delegates and the first general meeting will be held. The sections will meet at 9 A.M. on Sept. 3rd, 4th, 5th, and 6th. The proceedings will be diversified by various excursions and entertainments. The offices of the Congress are at No. 717, Prinsengracht, Amsterdam. The visitors' accommodation committee will secure rooms for members if application is made before August 15th to Dr. D. M. van Londen at the above address. Applications for membership of the Congress must be made not later than August 1st.

SANITARY WORK ON THE ISTHMUS OF PANAMA.

DURING the last three years some remarkable sanitary work, remarkable alike in its conception and in its result, has been undertaken on the Isthmus of Panama. Dr. W. C. Gorgas, in the *Medical Record* of May 18th, gives a succinct account of this work. He points out that when the United States took possession of the canal zone three years ago there were all the conditions necessary for the breeding of stegomyia and anopheles mosquitoes, that malaria, dysentery, and small-pox were prevailing among the people, and that yellow fever was present at Panama and Colon. Organised sanitary endeavour has now caused the disappearance of yellow fever and malaria has been held in check, but for 15 miles the canal belt is low and swampy, and in the other portions rain-water barrels and cisterns are plentiful, so that all conditions for the breeding of mosquitoes are at their best in a climate that is never cold. The presence of yellow fever, apart from the stegomyia, is due to the coming of non-immune whites in large numbers who contract and propagate the disease. The health authorities have furnished pure water, sewage systems and methods for the proper disposal of night soil, and sufficient hospitals for the care of the sick. They keep up an inspection of those who are non-immune, isolate cases of yellow fever in screened houses, and kill infected mosquitoes by fumigation. By ditching, draining, and oiling stagnant waters they have lessened the anopheles mosquitoes and the consequent malarial troubles. An efficient quarantine against infected localities is maintained at the ports of entry to keep out yellow fever and for 15 months there has not been a case of it in the canal belt. This is not a coincidence but a result of the sanitary measures taken. Dysentery has also been considerably controlled by, among other things, the provision of a good water-supply, so that we may congratulate all concerned in the sanitary administration in Panama upon great results.

EPIDEMIC CEREBRO-SPINAL FEVER.

DURING the last seven or eight days there has been some diminution in the notifications of epidemic cerebro-spinal fever. In Scotland during the week ended May 25th there were 19 deaths from this cause registered in Glasgow, 5 in Leith, and 2 in Dundee. In Glasgow the weekly report issued on May 24th showed that there were at that time 116 cases under treatment. In Belfast during the week ended May 25th there were 20 deaths from this cause registered. In London during the month of April one death of a patient belonging to Poplar was registered.

AS regards Hong-Kong, a telegram from the Acting Governor received at the Colonial Office on May 27th states that for the week ending May 25th there were 10 cases of plague and 10 deaths from the disease. As to the Cape Colony, the medical officer of health of the Colony states that for the week ending May 4th no further case of plague in man was discovered in King William's Town, but that on the 5th a European girl, aged 11 years, was found to be suffering from bubonic plague. The Department of Public Health of Queensland in a bulletin dated April 20th states that for the week ending on that date no case of plague occurred either in Brisbane or at Port Douglas.

THE annual dinner of the Indian Medical Service will be held in the Adams Room at the New Gaiety Restaurant, Strand, London, on Thursday, June 13th, at 7.45 P.M., when Surgeon-General Sir Benjamin Franklin, K.C.I.E., will preside. Officers intending to be present should communicate at as early a date as possible with the honorary secretary, Lieutenant-Colonel P. J. Freyer, 27, Harley-street, Cavendish-square, W.

Sir Arthur Rücker, M.A., D.Sc., LL.D., F.R.S., Principal of the University of London, will distribute the prizes to the successful students at Guy's Hospital on Thursday, July 4th next. The usual garden party will be given in the grounds.

Mr. David James Galloway, M.D., C.M. Edin., has been appointed an Unofficial Member of the Legislative Council of the Straits Settlements.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, MAY 28TH.

THE sittings of the eighty-fifth session of the General Council of Medical Education and Registration were commenced to-day at 299, Oxford-street, Dr. DONALD MACALISTER, the President, being in the chair.

New Members.

The following new members took their seats as Direct Representatives for England: Dr. Henry Langley Browne, introduced by Dr. R. Saundby; and Dr. Leonard Strong McManus and Dr. Henry Arthur Latimer, introduced by Sir John Williams. Dr. Norman Purvis Walker, introduced by Mr. Hodsdon, took his seat as Direct Representative for Scotland.

The President's Address.

The PRESIDENT then delivered his address. After making kindly allusion to the services of Sir Victor Horsley, Dr. William Bruce, Mr. George Brown, and Mr. George Jackson, who have ceased to be members of the Council, and giving a no less kindly welcome to Dr. Langley Browne, Dr. Latimer, Dr. McManus, and Dr. Norman Walker, who have taken their places, he said:—

As you are probably aware, I have been unexpectedly called by His Majesty to be the resident head of the University of Glasgow. The authorities of the University of Cambridge, to whom I owe my seat in the Council, and accordingly in this chair, have kindly expressed a desire that I should complete the term of five years for which I was last re-elected by the Senate. As the Senate is not limited in its choice to persons in continuous residence at Cambridge, and as I shall maintain a close connexion with that University, I have agreed to retain my membership of the Council as its representative. I have made such arrangements for the conduct of office business during the intervals of our sessions as will ensure that the commonwealth shall take no detriment on account of my greater distance from London. It may even be that some advantage will accrue from the opportunity afforded to your President of studying at first hand the position of medical education and practice in Scotland as well as in England. The Lord President of the Privy Council has just furnished us with an illustration. The University of Edinburgh has framed an Ordinance making certain changes in the course of study and examinations for medical degrees. On this Ordinance two of the three other Scottish Universities have offered to the Privy Council, as they are entitled by law to do, various criticisms, of which some refer to inter-university relations rather than to general principles, others perhaps to matters of substance. In regard to such general principles and matters of substance the Lord President invites an expression of opinion on the part of the General Medical Council. The Executive Committee has resolved to refer the ordinance to the Education Committee and the Examination Committee, with the request that they will respectively report to the Council whether the provisions of the ordinance are in conformity with its existing resolutions and recommendations on the subjects of professional education and professional examination.

It is with special satisfaction that I record the completion of the negotiations for medical reciprocity with the Province of Nova Scotia, to which, as you will remember, His Majesty in Council was pleased last year to apply Part II. of the Medical Act, 1886. The negotiations with the Executive Committee, to which the Council has delegated the duty of carrying into effect this part of the Act, have been conducted by the provincial authorities with the utmost goodwill and with the fullest desire to meet the requirements of the Council. As a result the committee has felt justified in granting recognition to Nova Scotian degrees and diplomas on terms which, while they fulfil the conditions of the Medical Act as regards sufficiency, are at the same time satisfactory to the Provincial Medical Board. The Board has, moreover, voluntarily undertaken to initiate legislation which will tend to raise still higher the efficiency of the medical curriculum of the province. The correspondence which has led to this gratifying result has been printed and published in the minutes of the Executive Committee. The admission of Nova Scotian qualifications to the British Register has already, as I understand, had the incidental consequence that Canadian medical graduates who have fulfilled the conditions applicable to the maritime province are now declared to be eligible for commissions in the Royal Army Medical Corps. The Australian States, which long ago entered into reciprocal relations with this country, are already in a position to offer similar advantages to their medical graduates. It is to be regretted that graduates of provincial universities in Canada other than those of Nova Scotia are still ineligible for appointments in the medical services of the Crown. It now rests with the Canadian provinces themselves to remove the disability. The Council, which has always taken a broad view of its responsibilities to the empire in general, will doubtless give the most favourable consideration to any overtures the provincial governments may make to this end. His Majesty has not yet been pleased to apply the Act to the Province of Quebec, as it is first necessary that the Privy Council should be more fully informed of the actual provisions of the local law affecting the admission to the provincial register of practitioners registered in the United Kingdom. We are told that the requisite inquiries are being made through the proper channels. Until His Majesty in Council is satisfied regarding the provisions in question the Executive Committee is unable to take further steps towards the recognition of Quebec degrees.

The Foreign Office has forwarded to the Council copies of the international agreement respecting the unification of the pharmacopœial formulas for potent drugs, which was signed at Brussels on Nov. 29th, 1906, by the diplomatic representatives of 18 states on behalf of the respective contracting governments. This agreement embodies, with slight amendments, the resolutions of the Brussels Conference of 1902. It includes the following reservation which, as chairman of the Pharmacopœia Committee, I ventured to suggest should be made on behalf of this country: "The Government of His Britannic Majesty declares that it reserves the right of introducing into the stipulations of the present agreement such modifications in detail as the progress of medical and pharmaceutical science may render necessary from time to time." In drawing up the next Pharmacopœia it will accordingly be incumbent on the Council, in the paramount interest of international uniformity and of public safety, to make certain changes in the formulas for a few poisonous drugs and preparations. The changes involved may not in all cases be deemed improvements, and if our own insular convenience only were in question might not at once be approved; but they are probably fewer and less important than other countries will be constrained under the agreement to make in the common interest of all. The reservation above mentioned, moreover, enables the Council, as the authority statutably responsible for the British Pharmacopœia, to modify the letter while observing the spirit of the agreement, so as to keep pace with the progress of medical and pharmaceutical science. The Committee of Reference in Pharmacy has had the agreement under consideration and has presented to the Pharmacopœia Committee a valuable report on the changes required to give it effect.

Two Bills, proposing amendments in the law relating to the practice of medicine and of dental surgery by joint-stock companies, which have already received the approval of the Council, have been introduced in the Upper House by Lord Hylton and have passed the second reading without opposition. They were supported in principle by Lord Halsbury, late Lord Chancellor, and by the Lord President of the Council on behalf of the Government. By consent they have been referred to a Select Committee, which will shortly sit to receive evidence from this Council and from other bodies interested respecting the abuses against which the Bills are directed and the sufficiency of the proposals therein contained for the purpose contemplated. The Registrar and your legal advisers are actively engaged in preparing for submission to the Select Committee a statement of the evidence in the possession of your Companies Bills Committee. A Bill to empower the Society of Apothecaries of London to confer on those who have passed its qualifying examination the title of "Licentiate in Medicine and Surgery" has passed through several of its stages in Parliament. Certain amendments in its terms, suggested by the Executive Committee in the interest of the Council, have been readily adopted by the promoters.

A question seriously affecting the position of members of the Council as a judicial body has been raised by a communication from the chairman of the Central Ethical Committee of the British Medical Association. The communication informs us that the annual representative meeting has decided that the Association should act as complainant in cases which might require to be brought before the General Medical Council; and that the Central Ethical Committee is the body whose duty it would be to consider whether a given case should be so brought and to prepare the case for our consideration. As many members of the Council (and of the Penal Cases Committee) are members of the British Medical Association, it appeared desirable that their position in regard to complaints made by the Association, if such were brought for inquiry before the Council (or the committee), should be made clear. I accordingly consulted our legal advisers, who are familiar with the *dicta* of the Lords Justices in cases (such as Leeson's and Allinson's) where the suspicion of bias or prejudice on the part of members of the Council has been alleged as a ground of appeal against its decisions. Their advice is that the proper course to be taken by a member of the Council who belongs to the Association is not merely to withdraw from the decision of a case in which the Association acts as complainant but to withdraw from membership of the Association altogether. The question of acting on this advice became urgent in my own case, when at the beginning of this month the Registrar reported that a formal complaint against a practitioner had been lodged at the office by a branch of the Association, and that the documents awaited my consideration in pursuance of the Standing Orders. As your President, I could not take even the first step towards a judicial inquiry so long as I remained a member of the British Medical Association. I therefore, without delay, sent in my resignation to the general secretary. So soon as my resignation takes effect I shall be able to look at the complaint; but I shall not be able to take the advice of the Penal Cases Committee upon the matter until the other members have also ceased to be connected with the Association. I have made the foregoing statement, after careful reflection, because it seems to me of the highest importance that members of the Council should be cognisant of the position resulting from the decision of the representative meeting of the Association. If that decision becomes operative, as regards either the central body or its branches, we who take any part in judicial inquiries have, in my opinion, no choice but to sever our connexion with the Association. However slight our connexion may be, circumstances might at any moment arise in relation to an inquiry wherein the Association was interested, which might be held to affect the impartiality of our judgment and so to invalidate our decision.

The Secretary for Scotland has been pleased to give directions, similar to those already given in England and Ireland, which will result in the notification to the Council of all cases in which registered practitioners are convicted in Scotland of crimes or offences punishable by fines. The thanks of the Council are due to the Government authorities for this aid to the performance of its disciplinary function. It happens, perhaps as a result of the better information at our disposal, that most of the penal cases to be brought before you this session have reference, not to allegations of "infamous conduct" but to convictions before the ordinary tribunals for crimes or other offences of various kinds. As in these cases the evidence of conviction is clear it is probable that you will have no great difficulty at arriving at a decision upon them. The striking diminution in the number of complaints concerning misconduct in a professional respect is a satisfactory feature of the present year. Certain decisions given recently in the Chancery Division of the High Court in connexion with our judgment in an inquiry held by the Council last year have raised legal questions of interest regarding the scope and meaning of the statutory phrase "infamous or disgraceful conduct in a professional respect." The Chancery decisions do not in form impugn the judgment of the Council or call in question its jurisdiction, but some of the points involved concern us so closely that I have asked the Council's solicitor to prepare a memorandum on the subject for our information. As we are advised that an appeal against the judgments is in progress, and as the cases are therefore *sub judice*, I propose that the memorandum should be communicated to the Council *in camerâ*.

At our last meeting you empowered the Executive Committee to adjust and to issue to the Council a new print of the Standing Orders, embodying therein such alterations, particularly with reference to our penal procedure and to the inspection and visitation of examinations, as the Council had by its resolutions directed or were consequential upon such resolutions. The committee has accordingly had prepared, and has approved, a complete edition of the Standing Orders in which such verbal amendments have been made as seemed necessary to give effect to the Council's intentions. Copies will be laid on the table and are now available for the use of members and of the public. For the Education Committee elaborate tables of statistics have been drawn up by the Registrar and Mr. King, with the assistance of the Branch Registrars, showing the ages at which practitioners registered during the year 1906 began and ended their curriculum. The committee will probably lay before you an analysis of these statistics and a report explaining what light they throw on the average length of the curriculum, and on the question of subdividing it into definite stages, which was referred to it last November. You will doubtless be of opinion that further statistical data, such as can be furnished only by the licensing bodies, are necessary in order to complete the information on which alone the committee can base a reasoned and reasonable solution of the question. The Practical Midwifery Committee, the recommendations of which were presented but not discussed during the winter session, has now received further replies and suggestions from licensing bodies. These will be duly communicated to the Council, and it will then be a position to adopt suitable resolutions on this important branch of professional education and examination.

In accordance with the resolution of Nov. 30th, 1906, I communicated to Sir Henry Howse and Mr. Alexis Thomson your acknowledgments of the valuable services they had rendered to the Council during their long tenure of office as assistant examiners in surgery at the Apothecaries' Hall, Dublin, and your desire to establish a system of rotation in the appointment of such examiners in future. From both have come letters expressing appreciation of the Council's consideration and concurring in the suggestion that rotation is desirable. Proposals will be made to you for the appointment of two Dublin surgeons, one to act for two years and one for four, as assistant examiners (and on occasion inspectors) for the Apothecaries' Hall. Their function is an important one, for through them the Council has to perform its statutory duty of maintaining the present standard of efficiency, and that not in surgery alone, at the examinations of this licensing body.

In conclusion, I have to congratulate the Council on finishing another financial year with a surplus instead of a deficit. But for the heavy expenses connected with the general election, expenses which are considerably increased by the introduction of the ballot system, the surplus would have amounted to £910, or a little more than last year. Of this sum, however, £870 were expended over the election, leaving a net balance of only £40. The actual expenditure on the enlargement of our chamber, and the improvement of our property, has for the time been met by means of the surplus in hand from last year. But it will next year have in whole or in part to be brought into ordinary account, and it therefore still behoves the Finance Committee to keep a watchful eye upon our outgoings, and especially on those connected with our ordinary sessions. There is good reason to expect that at the present meeting we shall easily be able within the limits of this week to overtake all the business in hand.

On the motion of Dr. NORMAN MOORE, seconded by Mr. MORRIS, the President was thanked for his address.

Business Committee.

The Business Committee composed of the President, Dr. Norman Moore, Mr. Young, and Sir Christopher Nixon was appointed.

Professional Examinations and Competitions.

Tables showing the result of professional medical examinations during 1906, results of professional examinations for qualifications in sanitary science, public health or State medicine, results of professional dental examinations, and competitions for commissions in the medical staff of the Royal Navy, the Army Medical Service, and the Indian Medical Service were received and entered in the minutes.

Apothecaries' Hall of Ireland.

Sir JOHN MOORE proposed the following motion:—

> That the Governor and Court of the Apothecaries' Hall, Dublin, be requested to furnish for the information of the Council a statement showing, in reference to the final or qualifying examination of that body: (1) the number of candidates who have presented themselves for the said examination in each year since the appointment of assistant examiners in surgery by the Council in May, 1897; (2) the number of candidates who have been successful at the said examination in each year since 1897; (3) the subjects in which the respective candidates presented themselves at each final examination during the said ten years; (4) the number of candidates rejected in each of the subjects of medicine, surgery, and midwifery; and (5) the number of times each rejected candidate has been re-examined during the past ten years.

Sir John Moore called attention in the course of his speech to the history of the Apothecaries' Hall of Ireland. He had himself noticed the result of the final examination since 1901, and he found that during the last six years 32 candidates had been examined for its Licence; of these, seven had passed. Let the members of the Council for a moment imagine all the machinery that had to be employed to license those seven men. He did not intend to put a slight upon the Apothecaries' Hall at all. If it ceased to license men for the medical profession and if it returned to its proper course of licensing pharmacists it would have, he believed, a very successful future before it. He thought they ought to get this information, because it was not all available from the books of the Council, and the question would soon arise whether representations should not be made to the Privy Council on the subject. He was aware of the fact that they could not make representations that the examination was insufficient, but they could make representations that the Hall, as a body, had so diminished in importance as not to require representation on the Council.

Dr. LITTLE seconded the motion.

Dr. ADYE-CURRAN expressed surprise that the motion had been brought forward. After its rejection last session it was in somewhat bad taste for Sir John Moore to bring it up again. If they had an Irishman to be hanged they always got an Irishman to pull the rope. There had been bad feeling for years between the Royal College of Physicians of Ireland and the Apothecaries' Hall of Ireland. However, during recent years there had not been a single fault found with the examinations of the Hall. Every inspector had complimented them on the manner in which the examinations were carried out. There was not a stricter set of examinations in Ireland. He asked the Council not to accede to this motion, because he did not think its information was really required.

After some discussion the motion was lost, 10 members voting for it and 13 against it. Nine members declined to vote.

On the motion of Dr. ADYE-CURRAN, Sir Lambert Ormsby, late President of the Royal College of Surgeons in Ireland, and Mr. F. Conway Dwyer, Fellow and examiner in surgery in the Royal College of Surgeons in Ireland, were appointed assistant examiners in surgery to the Apothecaries' Hall of Ireland, the former for a period of two years and the latter for a period of four years, in place of Sir Henry Howse and Mr. Alexis Thomson retired.

The Apothecaries' Society of London.

On the motion of Sir HUGH BEEVOR, Mr. Henry Percy Dean, L.S.A., M.B., M.S. Lond., F.R.C.S. Eng., was appointed assistant examiner in surgery to the Apothecaries' Society of London for a period of four years, in place of Mr. Peyton T. D. Beale who retired by rotation.

Nova Scotian Degrees.

A report was submitted from the Executive Committee stating that it had considered the conditions under which medical qualifications granted in the Province of Nova Scotia should be recognised for registration in the Colonial List of the *Medical Register* of the United Kingdom. The report further stated that on Feb. 27th, 1907, the committee adopted the following resolution:—

> That any person who holds (1) the diploma or licence in medicine, surgery, and midwifery granted after examination by the Provincial Medical Board of Nova Scotia, together with the licence to practise in that province; or (2) the degrees of doctor of medicine and master of surgery of the Dalhousie University, together with the aforesaid license to practise; or (3) the degrees of doctor of medicine and master of surgery of the Halifax Medical College, together with the aforesaid licence to practise, shall be entitled to be registered in the Colonial List of the Medical Register, provided he satisfies the registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886.

The PRESIDENT moved:—

> That the report of the Executive Committee on the recognition of Nova Scotian degrees and diplomas be received and entered in the minutes, that the registrar be directed to give effect to the resolutions therein contained, and that the Council record satisfaction at the establishment of reciprocal relations with the Province of Nova Scotia.

The motion was agreed to unanimously.

Restoration to Medical Register.

After consideration *in camerâ* the PRESIDENT announced that the Council had resolved to direct the Registrar to restore to the Medical Register the name of Hugh Stanley Revell.

Clinical Teaching in Medicine and Surgery.

Dr. LINDSAY STEVEN moved:—

> That a committee of this Council be instructed to obtain information as to the methods of clinical teaching in medicine and surgery in operation at the various teaching centres of the United Kingdom, with special reference to the numbers of students attending the individual courses, the relationship of the number of beds at the command of the teacher to the number of students attending his course, and the probable influence of the teacher being at the same time the examiner upon the size of his class, and to report to the next session of Council.

He said that in his opinion, in order to make teaching both in medicine and in surgery efficient, there should be a definite relationship between the number of students and the amount of clinical material such as hospital beds. He also thought that it was desirable that the clinical class should be relatively a small one. In this connexion he would refer to the reports on the Scottish Universities received a few years ago, in which certain remarks were incorporated by the visitor and by the inspector of the Council to the effect that in their opinion candidates, while well up in book knowledge, were really defective in the practical application of their art, and they recommended more individual attention to the clinical side and practical work. Young medical men had had to learn after they had qualified what they ought to have learnt in the hospital, and he thought that it was most desirable that such a committee as he had suggested should be appointed.

Dr. MACKAY seconded the motion, although he said that his feeling was that while in the end they would have to take up the questions which Dr. Lindsay Steven had brought before them, it was perhaps a little premature to do so until preliminary matters had been settled by the Council.

The motion was subsequently withdrawn.

The Council adjourned till Wednesday.

WEDNESDAY, MAY 29TH.

Penal Cases.

During the first part of the day the Council was occupied in the discussion of penal cases.

The Council and the British Medical Association.

A report by the Executive Committee of the Council on a communication from the British Medical Association was then received and entered on the minutes. The communication from the Association called the attention of the General Medical Council to the fact that if the Central Ethical Committee of the Association should take upon itself the duty of bringing penal cases before the consideration of the Council legal difficulties might arise from members of the Council being members of the Association or of its central committees or central council. The report of the Executive Committee contained the resolution of the Committee that no member of the British Medical Association should act as a member of the Penal Cases Committee of the Council in cases in which the Association or any branch of it was acting as complainant. It was decided that the report of the Executive Committee, which was unanimously agreed to, should be sent to the General Secretary of the British Medical Association.

THE LANCET

SPECIAL SUPPLEMENT

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND

Published in aid of the Appeal to be made on Sunday, June 9th, 1907.

TWENTY times already THE LANCET has published its Annual Supplement on behalf of the Metropolitan Hospital Sunday Fund. For thirty-five years the Collection has been made in the places of worship of all religious denominations in London and its suburbs, and in localities beyond those suburbs, on behalf of the noble medical charities of which not Londoners only but all Englishmen are justly proud. Once more THE LANCET urges its appeal, and if our Supplement may be said in its present issue to attain its majority, it is appropriate that it should find its responsibilities increased by circumstances.

On the present occasion it is our endeavour to direct the attention of those into whose hands these pages may fall to the need of the Hospitals of the Metropolis for help; to remind those thousands of friends whom the Metropolitan Hospital Sunday Fund has already won that now is the time to give fresh proof of their goodwill; and to win for the Fund new friends who may vie with the old ones in proving their claim to the title. Of new friends in this present year of 1907 the Metropolitan Hospital Sunday Fund stands truly in need, for it has endured sad loss during the past twelve months. Every year obliterates from the roll of London's citizens the names of good and generous men who have helped to make the burden of the poor lighter in their days of sickness and pain, and among these the name of Mr. George Herring will ever stand conspicuous.

The late Mr. Herring

died on November 2nd, 1906, and while we dwell in grateful recognition upon his charity we hope that the example which he set may live after him. It is for those now surviving him to bring about that which he would most have desired—that his loss shall not be irreparable. In 1899 Mr. George Herring first contributed a donation of £10,000 to the Metropolitan Hospital Sunday Fund, and he repeated his generous gift in 1900. After that year he adopted the method of stimulating others which proved so valuable to the Fund. Possibly it was suggested to his mind by the sporting instincts of his younger days, and it certainly had that sporting element in it which appeals to many of our countrymen. He pledged himself to add to the amount collected in places of worship and in the City a sum equal to one-fourth of its total. The proviso that he should not thus be called upon to pay more than £25,000 was never called into operation, but at the time of his death he had enriched the Fund directly to the extent of over £78,000. Mr. Herring's magnificent legacy to the Fund, which approaches, and may even pass £750,000, remains as a permanent benefit and a princely memorial to his munificence, but his living example is gone, and living endeavour is wanted to replace his efforts. It would not be easy to say to what extent he increased the Fund indirectly, but his pledge afforded to all who gave the pleasant knowledge that their donations, whether great or small, would bear immediate fruit to the extent of 25 per cent., and it is impossible not to believe that some were influenced by the fact. May they now remember that Mr. Herring has died since last they contributed, and may they make good the deficit which otherwise will be felt by the Hospitals and by those whom the Hospitals assist. In other words, let them select a sum greater by, at least, one quarter than the amount of their last year's gifts, in deciding how much they shall contribute to this year's Offertory. It may not be possible for all to do this; it is not likely that the suggestion will meet the eyes of everyone who gave last year and who will give on the present occasion, but a general increase of the public generosity will be required if the efficiency of the Hospitals is not to be impaired.

The Late Mr. Wakley and the Development of the Fund.

Another prominent friend of the Hospitals and of the Metropolitan Hospital Sunday Fund, whose death has been mourned since that of Mr. George Herring, was Mr. Thomas Henry Wakley, the Senior Editor of THE LANCET and the eldest son of its founder. Imbued throughout his life with a keen and practical interest in all that pertained to the medical profession, he had watched the birth and growth of the Metropolitan Hospital Sunday Fund, of which his brother, Dr. James G. Wakley, was one of the original founders, and throughout the period during which our Supplement has been issued he personally supervised its production, using as a guide his knowledge of the working of the Fund acquired as an active and assiduous member of its Council and of its General Purposes Committee. When we consider the growth of the Hospitals themselves, and the huge increase which has taken place in the field in which their work is performed, we can easily see that one who had enjoyed the long life of Mr. Wakley must have been more impressed by the never-diminishing needs of the institutions themselves than by the success of any appeal made on their behalf. In contrasting the London of 1849 with that of the reign of Charles II., Lord Macaulay, in Chapter III. of his History, drew a vigorous picture of modern civilization as he saw it around him, and of the comparative barbarism of the later portion of the 17th century. Of the growth of London since that date he wrote, as if with pride, "The inhabitants, who are now at least nineteen hundred thousand, were then probably little more than half a million"; and in describing its extension in all directions he said, "Chelsea, which is now peopled by more than forty thousand human beings, was a quiet country village with about a thousand inhabitants. On the north cattle fed and sportsmen wandered with dogs and guns over the site of Marylebone. . . . . On the south the Capital is now connected with its suburb by several bridges, not inferior in magnificence and solidity to the noblest works of the Cæsars."

That the historian should have been justified in classing what we now should call "London south of the Thames" as a "suburb," is a vivid illustration of the difference which half a century has wrought. Let us remember that this difference arose in the life-time of Mr. Wakley, in order that we may appreciate what the work of the Hospitals has been in whose prosperity he took so keen an interest. The Hospitals have had to keep abreast of the growth and progress around them, and the need of the poor will not diminish while London is trading with the whole civilized and uncivilized world.

The Increasing Demand.

We are reiterating a tale that has been told not twice but many times in these columns, and if we lay stress upon the fact of London's increase in population we have supplied the reason for a reiteration which should be couched, if it were possible, in stronger terms from year to year. The ever-widening circle of those who depend upon the Metropolitan Hospitals calls for a provision of the necessities imposed by the progress of modern science. There is a demand for buildings, for operating theatres, for instruments and apparatus of all kinds, for nursing and service of every description, which must all be in conformity with the highest standards.

The rapid improvement in science, contemporaneous with the recent growth of the population, must be remembered, while we remind our readers of a modern development for which they are in part responsible, and which they will not, we know, desire to see arrested. Public benevolence as we understand it in 1907 is largely an outcome of our civilization. There were kind-hearted men, all honour to their memory, who founded the great Hospitals of London in the old days that have passed away, but none can say that the attitude of the public mind was what it now is towards poverty and suffering. Let us remember the small bands of men and women who first organized attacks upon the slave-trade not so very long ago, and the Howards and the Frys who called public attention to our prisons. The increase of London's population since the age of the Stuarts, and again since the commencement of the Victorian era, the improved social conditions, the altered sanitary surroundings and demands of its inhabitants, have taken more than two centuries to bring about, and the change, rapid of late years, was at one time more gradual and more easily observed and controlled. Perhaps if there had been during all those years the same public demand for philanthropic enterprise as now, if the support of hospitals organized like those of to-day had been a recognised form of universal almsgiving—if, for example, the Metropolitan Hospital Sunday Fund had been first instituted by Nell Gwynne when she promoted (or did not promote) the foundation of Chelsea Hospital—who shall say that the growth of the Hospitals' resources might not have kept pace with the expansion of the sphere within which their beneficence was to be exercised? What might have been the result, too, of donations and legacies invested in suburban land in the days when, as Macaulay reminds us, Oxford Street (surely not the Oxford Road) ran between hedges?

The organization of charity, however, so far as this has been achieved (and much remains to be done), the periodical concentration of public attention upon the Hospitals of London, and the energetic public appeals now made on behalf of individual institutions, belong to our own times. The increase of London's inhabitants by some millions has come more or less with a rush, and who can justly express surprise or dissatisfaction if the end to be desired is not yet reached and if the Hospitals are "begging" with insistency and with tales of poverty that do not diminish. They live from hand to mouth through no fault of theirs, and if they fail to attain the ideal position which their well-wishers desire for them, or if from time to time they permit their expenditure to exceed their incomes, the remedy is still the same. Give! Give freely and without stint or economy. The Hospitals will practise economy when it comes to spending what they receive. The Metropolitan Hospital Sunday Fund will see to that, and will itself exercise prudence and economy in administering the resources placed at its disposal; but the gifts of the public need to be regulated by no consideration that the amplest charity will ever be either superfluous or misplaced.

The Ever-growing Population.

It may be suggested that as London spreads so its wealth increases, and that from the fringe of villas which marks the enlargement of its borders, from those ever-rising blocks of flats and rows of houses which spring up where slums have once stood, there should flow almost automatically enough money to compensate for any augmentation of the working classes and of the horde of casual workers and non-workers who are chronically and irremediably poor. If, however, any think seriously that the increase of London's population has been accompanied by such an increase of wealth that the Hospitals might have been expected to secure financial benefits corresponding to the fresh demands for their help, let them reflect that the influx during the past twenty-five years has taken place from the poorer classes of society. Just as the Hospitals open their doors to all alike, excluding none on account of race or of religious opinion, examining the moral character of none and taking no account of a criminal record, so in like manner London has been a Mecca for pilgrims of all ranks and degrees of riches or of poverty, with this difference, that, unlike the pilgrims who visit a shrine and depart, those least likely to make desirable inhabitants come to stay. London has attracted, as if by some magnetic influence, the energetic worker (with or without capital) and the confirmed idler, the artizan in search of better wages, and the unskilled labourer from rural districts together with the degenerate and the vagrant in search of relief for the "unemployed." It has opened its doors (with the exception of the enforcement of a recent statute of limited application) to a miscellaneous crowd of aliens, desirable and absolutely undesirable, healthy and diseased, from every country under the sun. In such circumstances it would have been nothing short of miraculous if the power of the Hospitals to deal with the human suffering at their doors had increased in proportion to the swelling crowd of those congregating to seek admittance, and the governing bodies of Hospitals *do not claim to work* miracles any more than do the physicians and surgeons who perform their duties in the wards. It is, we fear, utopian to suggest that the large number of those who come to us as strangers and who accumulate wealth in our midst should give with sufficient liberality to meet the demands which newcomers like themselves but in humbler social grades make for charitable assistance. We would, however, point out to those practising their callings with success, or, perhaps, piling up fortunes in London, but who nevertheless are recent sojourners, that the Metropolitan Hospital Sunday Fund enables them to offer some return for the hospitality which we Londoners so freely accord to them. Let them look, moreover, at the list of Hospitals to which the Fund distributes the money subscribed, and they will see included in it institutions the titles of which proclaim the nationalities of those for whom they are primarily designed side by side with our native institutions. Let them visit the Hospitals of London that are purely British in title, and they will find in their wards foreigners of every description.

STATISTICS OF HOSPITAL WORK IN LONDON DURING THE YEAR 1906.

* We reproduce the term "General Hospitals" as employed by the Council of the Metropolitan Hospital Sunday Fund.

It is this unquestioning charity of the Hospitals which drains their resources and which at the same time strengthens their claim upon the generosity of all. Still more forcibly should this claim be recognised when it is pressed in the places of worship of all congregations of every shade and variety of religious belief as an appeal to the common humanity of those who assemble within their walls. Poverty and sickness; need and pain—if only these two causes are united they are all-sufficient. No questions of character or of religion are raised when human life is or may be at stake. Probably this fact was brought forcibly home to some who had not reflected upon it before when they read recently of the murderer of Mr. William Whiteley being taken straight to a Hospital, tended there, and nursed back to life. They saw in the newspapers accounts of the police officer who watched over the wretched Rayner's bedside, and they talked of the incident as if it were an extraordinary one.

It was nothing of the kind; the policeman in charge of the would-be suicide, or of the burglar who has injured himself in trying to escape apprehension is, so to speak, a "common object" in Hospital wards. A few years ago we published in one of our Annual Supplements "testimonials" from grateful patients in the principal Hospitals of London, and our Commissioner, in describing his experiences while collecting them, narrated how in one Hospital he had come across a man lying in bed while a policeman kept watch and ward over him. He made inquiry, and found that this man had broken his leg in jumping from a wall after breaking open and robbing—what?—a collecting box for contributions to the very Hospital in which he was being tended. The Samaritan tended the wounded stranger who had fallen among roadside thieves; the Hospital in this instance tended him who had been trying to filch from it the money essential to its subsistence.

Who should give.

During the years in which THE LANCET has issued its Supplement we have chronicled subscriptions which amount to a goodly sum. In many years £40,000 has been exceeded, and £40,000 per annum is a large income to raise and to distribute, but when we look at the donations of £1,000 or more, and when we note the large amounts contributed by some of the Churches which are known to have rich congregations we may well feel doubtful as to whether the giving to the Hospital Sunday Fund is in the least general among our population. There are few of those removed from actual poverty who cannot give something, whether man, woman, or child; very few to whom to do so would necessitate an act of self-denial of a serious character. A few ounces of tobacco, a seat at a place of amusement, a yard or two of ribbon or a few ounces of sugar plums, these are the abnegations which would enable "quite poor people" to exceed the average donation of the London citizen to the Fund. The Metropolitan Hospital Sunday Fund has earned the goodwill of rich givers like Mr. George Herring because it has done its work

with care and efficiency, but it was instituted not merely to convey the donation of the wealthy man, but in order to collect the anonymous offerings of all who in a particular week attend religious worship, and of all who on the day set apart for rest enjoy that leisure which the work of the week has earned for them. To many of these a substantial gift means very little in the way of self-denial. But whether it does so or not, is not the object worthy of the sacrifice? That object is to relieve the poor when overcome by bodily suffering, or incapacitated by injury or disease; to help those to whom no relief can come save only if charity will provide it, and for whom bodily weakness and disease mean incapacity for work, helplessness, and starvation. Surely such an object should appeal to men

which amount to a goodly sum. In many years £40,000 has been exceeded, and £40,000 per annum is a large income to raise and to distribute, but when we look at the donations of £1,000 or more, and when we note the large amounts contributed by some of the Churches which are known to have rich congregations we may well feel doubtful as to whether the giving to the Hospital Sunday Fund is in the least general among our population. There are few of those removed from actual poverty who cannot give something, whether man, woman, or child; very few to whom to do so would necessitate an act of self-denial of a serious character. A few ounces of tobacco, a seat at a place of amusement, a yard or two of ribbon or a few ounces of sugar plums, these are the abnegations which would enable "quite poor people" to exceed the average donation of the London citizen to the Fund. The Metropolitan Hospital Sunday Fund has earned the goodwill of rich givers like Mr. George Herring because it has done its work

they are ill, and they have no money because they cannot work. The intervention of the Hospital saves them. The degree of success achieved in that intervention will vary with the patient's case; the degree of gratitude will differ between one patient and another according to temperament. One question, however, should follow, either to be replied to by the patient, or for the interlocutor himself to supply the answer, "What would have happened if there had been no Hospital?" The nature of the probable answer we leave to our readers who may care to imagine the scene which we have suggested, and we add the further question, "What would happen to the Hospitals without money?" The Metropolitan Hospital Sunday Fund supplies the Hospitals with part of their incomes, a substantial item which for many years they have learnt to expect regularly, with the hope always of a possible increase in the sums allotted. We ask that a generous and general rise in the gifts of individuals and in the number of those giving may cause that hope to be realized in the present year.

TABLE SHOWING THE RESULTS OF COLLECTIONS SINCE THE COMMENCEMENT OF THE FUND.

Year.	Totals.	Donations.	Year.	Totals.	Donations.
1873	£27,700	£1544	1890	£42,914	£3391

1887	40,607	4130	1904	63,064	15,143
1888	42,579	3300	1905	76,579	29,425
1889	41,744	3432	1906	65,075	18,441

1884. Including £4500 from the International Health Exhibition.

1885, 1886, 1887. Including three donations of £1000 each from Dr. James Wakley, Editor of THE LANCET.

1891. Including £5000 from the late Duke of Cleveland, &c.

1894. Including a legacy of £5000 (less duty) from the executors of the late Mr. W. J. Whitaker.

1895. Including £10,000 from Messrs. Barnato and friends; £5400 from the Stock Exchange; £1000 from Lord Iveagh; and £1000 from Mr. J. B. Robinson.

From 1891 to 1895 Sir Saville Crossley, Bart., P.C., M.P., gave an annual donation of £1000, and since has divided his contribution between this Fund and King Edward's Fund.

1897. Jubilee year. H.R.H. the Prince of Wales started a Special Fund for Hospitals.

1899. Including £10,000 from Mr. George Herring, and £1050 from Mr. J. Lane Densham.

1900. Including a further £10,000 from Mr. George Herring, £1050 from Mr. Thos. King, and "F. H." £1000.

1901. Including a further £10,000 from Mr. George Herring, and £4000 from Sir F. Cook, Bart., M.P.

1902. Including a further £11,575 from Mr. George Herring, and £1000 from Mr. Charles Morrison.

1903. Their Majesties the King and Queen, with most of the other Members of the Royal Family, attended at St. Paul's Cathedral. Including a further £12,322 from Mr. George Herring.

1904. Including a further £11,925 from Mr. George Herring.

1905. Including a further £12,400 from Mr. George Herring, and £12,500 from the executors of Mr. F. W. Cook.

1906. Including a further £11,000 from Mr. George Herring and £5000 on account of the legacy bequeathed by Mr. Herbert Lloyd.

There can be no doubt that the influence of the Metropolitan Hospital Sunday Fund, together with the income which the public intrusts to it annually for distribution, has steadily increased, and that it owes its growth to the confidence which it has earned by what it has done. In the absence of any Central Board directing and controlling the management of the Hospitals as a whole, the Council of the Fund has made its influence felt in the conduct of various institutions. It has accompanied the distribution of the amount intrusted to it with suggestions and criticisms, in such a manner as to lend weight to its recommendations. In this way it has exercised supervision over expenditure and has laid down for the guidance of all the principle that a pound of revenue is expected to produce not less than a full pound's value of that which a Hospital should supply. It is the knowledge that its subscribers "get their money's worth" which wins contributions for the Metropolitan Hospital Sunday Fund from those who recognise the fact that economy and organization combined render charity effective, whereas indiscriminate and ill-directed almsgiving will only result in waste of money and energy. It is to the practical man who is a man of business as well as a benevolent citizen that the Fund commends itself as representing order, fairness, and economy in the distribution of limited and valuable assets among those entitled to enjoy them.

The Appeal is to All.

When we ask for contributions to the Metropolitan Hospital Sunday Fund we confine ourselves to no rank or division of the community. We believe that a large proportion of the class that benefits directly by the Hospitals can give of their small means because, leaving out those who are absolutely destitute, there is a considerable population of working men and women who, in their day of need, if it should ever come, will be helped by the Hospitals out of all proportion to any gift that they may ever have brought, and who, in their time of health and of comparative prosperity, should do what they can to provide aid for their fellow workers less fortunate than themselves. We do not ask them to give in order to provide or to assist Hospitals for their own reception, or to regard their gifts as maintaining institutions into which they will be received as a right or as the result of their own prudence. We prefer to urge upon them that the Hospitals are charities which they, in health and therefore comparatively affluent, help to support for

SUMMARY OF TABLES.

Total	£87,549	142,245	45,739	71,597	10,975	9,477	9,255	6,552,555	454,002

and women alike, and to children as well as to those who are of riper years. In all these also self-denial may be supplemented by a little effort. There is ever a little work to be done on behalf of a good cause; supporters of the Fund should not be content with giving themselves, but should induce others to do so too, reminding all who might otherwise forget, and winning for the Fund those new friends of whom it can never have too many.

It is not difficult, by the way, to forget; and it is always easy to plead forgetfulness. There are some who attend a place of worship but who only go provided with their usual offering, something which custom has perhaps reduced to a minimum. These surely may be reminded that Hospital Sunday is an occasion for exceptional generosity. Some may be prevented from attending Divine worship in the particular week in which Hospital Sunday occurs. This is no reason why their alms should not be intrusted to the hand of someone who may have recalled the needs of the Fund to their slumbering memories. Many leave London for the day on Sunday and attend no place of worship at all, or, in pursuance of what has now become a fashion of wide influence, leave London at the end of the week not to return until Monday morning. It is not for us to criticise them or to question their motives; but we would ask them not, in their absence, to forget those to whom health means the power to earn wages, and upon whose wages depends the very existence of their homes. We ask for a substantial gift from these absentees, and we earnestly beg all who are able to do so to remind them of a duty the performance of which should be a privilege and a pleasure.

The Inducements to Give.

Do any hesitate to give on account of a feeling of ignorance as to the work in aid of which the Metropolitan Hospital Sunday Fund craves their alms? Or do any of those who would be willing to try to induce others to contribute lack arguments wherewith to enforce their recommendations? The strongest arguments, the most convincing proofs that could be supplied cannot be brought before all, for it is not possible that the millions who might contribute should visit the Hospitals and see for themselves what goes on within their wards. It would be very interesting, however, for them, and a pleasant task for those conducting them, if all these uninformed or indifferent ones, some of them leading lives of extravagance or of luxury, could be taken through the wards of one or two of our principal hospitals, and could be directed to pause from time to time beside a bed, and to ask a few questions of its occupant. The stories which they would hear would vary in their details, and in some instances the patients would be more free in their confidences than in others. The main outline would, however, be often the same—a life of hard work interrupted in the monotonous course of its routine by the onset of painful disease or by some serious occurrence; possibly an accident, perhaps a crime of violence committed by another. Some of the patients are wretchedly poor, some in possession of regular work are in fair circumstances while they can work, and some receive wages which, if treated thriftily, might enable them to receive private medical aid; but all are in the same plight, they cannot work because

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 30th, 1829.

INFLATION OF THE LUNGS OF INFANTS.

AT a late meeting of the French Institution, a case was communicated, in which a new-born infant was aroused from a state of asphyxia by the insufflation of air. A child, just born, was brought to M. Portal for the purposes of dissection; while preparing for this, some short time after receiving it, it occurred to him to blow for an instant into its mouth. In two or three minutes, heat returned, the circulation recommenced, the heart began to beat, and the supposed corpse was restored to the parents a lively infant. A similar circumstance is said to have once occurred to an anatomist at Lyons.

CLIMATE OF EGYPT.

Dr. PARISET, a French physician, who has been residing for several months in Egypt, for the purpose of making observations on the climate, gives it as his opinion, that the notion generally entertained of the insalubrity of that country is erroneously founded. He considers Egypt as, in reality, a very healthy country, and that the air is only vitiated in some parts by the absolute want of the most simple sanitary measures. The carcases of animals, for instance, are every where abandoned to putrefaction, even, indeed, in the *very centres of the most* populous towns. He states that he ascertained, during his residence at Assouan, that the plague is not endemical in Nubia, and that the disease so termed, is only a species of intermittent fever.

MEDICINE AND THE LAW.

Milk and the Farmer.

AT Enfield recently a case was heard in which a retail milk dealer was summoned by an inspector under the Sale of Food and Drugs Acts for selling to his assistant "new cow's milk" which contained 14 per cent. of added water. At the same time there was a summons also taken out by the inspector against the farmer who sold the milk to the retailer for supplying that which was not of the substance and quality demanded by the purchaser, and the two cases were taken together. A discussion arose as to whether the contract to supply "new cow's milk" to his customer was a warranty on the part of the farmer upon which the retailer might rely as a defence to the prosecution, and points in connexion with the procedure adopted were raised which, it was stated, would eventually be referred to the Divisional Court. The result of the hearing, however, so far as the magistrates were concerned, was that they dismissed the summons against the retailer on the evidence, holding that he had not been guilty of adding water to the milk and convicted the farmer of doing so. Another case was then heard against the farmer, in which the inspector had gone on another date to the railway station to which the farmer had consigned milk for the retailer already mentioned and had there taken samples from a churn with the result that these on analysis were shown to contain added water to the extent of 8 per cent. In this case also the bench convicted the farmer, ordering him to pay in each case a fine of 10*s.* with the costs, including the fee of the analyst. The bench called attention to the conduct of the farmer in sending milk by rail without sealing or locking the cans, an explanation of which was suggested by the inspector under the Sale of Food and Drugs Acts. His view was that farmers prefer to send their milk thus by rail without securing the lids of the churns, because if it is afterwards shown to have reached the consignee in a defective condition they can put forward the explanation that it has been tampered with in course of transit, a defence which obviously would not be open to them if they rendered such interference impossible. As the intervention of the inspector in the circumstances described was questioned on the part of the defence no more need be said with regard to a point which is purely a legal one. With regard to the locking of churns, it is obviously of importance to the public that milk should be liable to examination at any stage of its conveyance from the cow to the ultimate consumer at which adulteration can be detected and brought home to those responsible for it. The task of inspection and of protecting the public will, however, be simpler and more effective if during one of those stages—that is to say, during a journey by road or rail—theft and adulteration are rendered impossible. To send milk in a sealed or locked can can hardly be prejudicial to a farmer or to a milk dealer, and it is not usual with regard to other goods to intrust them to carriers without some corresponding precaution.

The Case of George Edalji.

It was inevitable that the Home Secretary's decision in this case should be regarded as a compromise with justice, and Mr. Gladstone must have felt very sure of his ground indeed before, by withholding compensation to a man who had been admittedly punished in error, he exposed his department to further public censure. Our distinguished *confrère*, Sir Arthur Conan Doyle, who has throughout been one of Mr. Edalji's most stalwart champions, is now vigorously combating the assumption that Mr. Edalji wrote the various anonymous letters used at his trial, and to the ordinary mind his arguments are very convincing.

ASYLUM REPORTS.

Barnwood House, Gloucester (Hospital for the Insane) (Forty-seventh Annual Report, 1906).—The number of patients treated in the hospital during 1906 averaged 147 (55 males and 92 females). There were 44 patients (14 males and 30 females) admitted during the year 1906, this being the highest admission rate for the last 30 years. Dr. J. G. Soutar draws attention to the unfavourable nature, from the recovery standpoint, of the maladies from which the male patients usually suffer. For example, in the year under review, only one of the male admissions showed any prospect of recovery. He goes on to say that he has found in recent years "that insanity among the male patients from 40 years of age upwards has, in an increasing number of cases, been associated with ascertainable arterial degeneration. These early 'senile changes' are still comparatively rare amongst the women. In the case of most of the men alcohol or syphilis may be excluded as a condition precedent to the arterial changes, but we find them amongst those who have struggled and striven often successfully and with little relaxation in arduous mental work. In other cases it would seem as if excessive devotion to athletic exercises, carried on beyond the elastic years of youth, led, in those predisposed, to old age arteries in middle-aged men." As to the causation, the medical superintendent reports that a hereditary tendency to mental and allied nervous troubles was ascertained in 47·7 per cent. of the admissions. 30 persons (11 males and 19 females) were discharged during 1906 and of these only 12 (four males and eight females) had recovered. Two female patients were discharged relieved and of the other discharges seven males and nine females left uncured. Six males and two females died during the year, all from natural causes. Thus the recovery rate is only 27·2 per cent. on the admissions, which is low compared with the average recovery rate of the past five years, which is 45·2 per cent. Dr. Soutar accounts for this decrease in the recovery rate in that during recent years there has been a marked falling-off in applications for the admission of acute cases. If this is the case it is to be deplored, considering the high position that this hospital holds and the fact that much charitable work is done by it, for "the committee of the hospital are always ready to receive persons from the educated classes suffering from recent mental disorder at low rates of payment. No case of this type is refused admission, but it is quite extraordinary how few applications are received. We have oftener than we like to fill our beds with chronic cases who can no longer pay the fees required elsewhere but can still easily afford to pay us at remunerative rates. Many of these patients are intelligent and interesting members of our community, they offer points for study and consideration, and in various ways much can be done for them, but they cannot be cured. We reluctantly accept them in lieu of acute cases, for the accommodation of whom there has recently been so little demand." Four patients have been maintained gratuitously and 60 others below the average cost of maintenance. The committee states that the sum of £4833 was invested in the purchase of £5500 stock as an addition to the Pension Fund which is now represented by £36,094 in consols.

the reception of others worse off than they are. We hope for their sakes that they will never need the aid afforded; but if ever they chance to do so their gifts should thereafter take the form of thankofferings. But though all can help according to their means, in the main the Hospitals must always be the gift of the richer to the poorer, bestowed by the class which cannot expect to benefit directly from its generosity upon those who without that generosity must suffer unhealed and perhaps die. We have used the word "directly," because indirectly every man who calls in medical or surgical aid benefits from the training which his medical attendant has obtained from the Hospitals and which could have been imparted to him nowhere else. We do not forget, also, that the rich man may find himself the inmate of a Hospital at any time when some sudden emergency arises calling for his reception. He may, for example, be the victim of an accident in the streets, and then he will be benefited directly by an institution to the upkeep of which he may have contributed. What would be the feelings of one who on such an occasion found himself tended and brought back to life without ever having done anything to make the hospitals efficient? What would be his position after receiving that aid which can be given promptly and surely in Hospitals only? He would, indeed, feel himself the recipient of charity not intended for him, but bestowed upon him with the same freedom as upon others. He might be one of those who at times criticise unfavourably the never-ceasing appeal for pecuniary aid to our medical charities—such appeals, for example, as we are urging now on behalf of the Metropolitan Hospital Sunday Fund. He would not when lying in the Hospital ward complain because the latest, the best, and perhaps the most costly appliances of science had, in hands skilled to use them, warded off death. He would hardly then grudge to the poor men lying around him that measure of comfort which the Hospital allowed him to share with them.

Nevertheless, although we may glance at such possibilities as these, we do not ask those whose circumstances allow them to give to be generous simply because they may some day profit themselves thereby, either directly or indirectly. That would not be generosity at all; it would be a payment made after calculating the prospect of obtaining advantage from it. The real claim must be upon the charity of the giver; the true appeal must be to his heart, not to his head. It is to the poor that he gives, because they are poor, and because when struck down by injury or by disease they are helpless so far as their own resources are concerned, and he must give without hope of reward, save in the consciousness of his good action. In giving to the Fund, moreover, he knows that his charity will be distributed with justice and economy, so as to insure the best possible results, for, as we have said above, and now repeat, the Metropolitan Hospital Sunday Fund represents order in the distribution of charity.

THEREFORE GIVE.

The appeal is to all; therefore give. The rich should give out of their superfluity, and not only because they are rich, but because they are themselves benefited by the Hospitals. The poor should give out of their scanty means, relying upon their numbers for their influence. The shilling of the individual poor man, however steadily contributed, can never repay the Hospital for the expense that is incurred if he becomes an inmate; but out of London's 7,000,000 inhabitants there must be a third who could pay an annual shilling regularly to the Fund, and the income represented by such a subscription would restore all the Hospitals to solvency. To the benevolent man no scheme should make a surer appeal; to the practical man it must appear as a vast economic agency.

WE ALL SHOULD GIVE.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

Audited and found correct, this 24th day of November, 1906.
(Signed) W. H. PANNELL & Co., *Chartered Accountants*, 13, Basinghall-street, E.C.

*** *In the preparation of the voluminous statistics of hospital work which have been here digested and exhibited in collected form (and which have been specially supplied to us in response to our applications, and are quite independent of any returns made to the Metropolitan Hospital Sunday Fund Committee), we have been greatly indebted to a large number of secretaries and other officers of the various medical charities of the metropolis. To them we desire, as on many previous occasions, to tender our sincere thanks.*—Ed. L.

VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—

Northern Command: Rifle: 5th Volunteer Battalion the Durham Light Infantry: Surgeon-Major Andrew Arthur Abraham.

Scottish Command: Artillery: 1st Fifeshire Royal Garrison Artillery (Volunteers): Surgeon-Major Robert Balfour Graham. *Rifle:* 5th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant-Colonel James Mill.

THE ROYAL NAVAL HOSPITAL, STONEHOUSE, PLYMOUTH.

Inspector-General H. Mackay Ellis, Director-General of the Royal Navy Medical Service, made his annual inspection of the Royal Naval Hospital, Stonehouse, on May 21st and 22nd. After the inspection of the medical and surgical wards he expressed his satisfaction with the result of the visit. The Director-General was accompanied by Inspector-General H. T. Cox, R.N., and the heads of departments.

Correspondence.

"Audi alteram partem."

MELÆNA NEONATORUM.

To the Editors of THE LANCET.

SIRS,—In your annotation on the above subject in THE LANCET of May 25th, p. 1443, it is suggested that melæna neonatorum may "be one of the many pathological conditions produced by the virus of congenital syphilis." This statement is supported by the authority of Dr. Balzer of the St. Louis Hospital, Paris, who states in his article on Syphilis in Brouardel and Gilbert's "Traité de Médecine," 1906, that some newly born children succumb to intestinal hæmorrhage associated with purpura, a condition known as "syphilis hæmorrhagica neonatorum." Dr. Still in his lectures on "Infantile Syphilis" also refers to this condition. Whether melæna neonatorum is always due to congenital syphilis may be open to dispute, but this diathesis is probably responsible for most cases.

I am, Sirs, yours faithfully,

New Cavendish-street, W., May 26th, 1907. C. F. MARSHALL.

CONVALESCENT HOME OF ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

To the Editors of THE LANCET.

SIRS,—May we ask you for space to appeal to Cambridge men and their friends for help in providing Addenbrooke's Hospital with a seaside branch for convalescents, such as is now felt to be a necessary equipment for every great hospital? These seaside branches are quite distinct from the ordinary convalescent home to which admission may be obtained through subscribers' letters for people needing merely rest and change of air. They are intended precisely for those whom such homes must of necessity exclude—viz., those who still need surgical care and dressings, including men, women, and children from three years old. The patients are nominated by the hospital staff and have all been under treatment at the hospital. There are thus no trivial cases. The removal of these patients at the earliest possible moment after operations or other severe illness gives much needed relief to the hospital wards, while the bright seaside and open-air life completes the work of restoration as nothing else could.

In response to an appeal made eight years ago by the medical and surgical staff of Addenbrooke's Hospital for such a branch the work was begun in a hired house by the seaside. The generosity of a few friends provided funds enough to try the experiment for some years and its success has been even beyond their hopes. But these funds are now exhausted; the lease of the temporary home at Dovercourt has come to an end; the committee has decided to build (no house not planned for this object being really suitable) and has secured an admirable site at Hunstanton. All that is now needed is £3000, towards which £600 have already been given or promised. Donations will be gratefully received at Barclay's Bank, Cambridge.

We are, Sirs, yours faithfully,

L. DE BUNSEN,
Honorary Treasurer of the Home;
DONALD MACALISTER,
Consulting Physician to Addenbrooke's Hospital.

Cambridge, May 18th, 1907.

SANITARY AUTHORITIES AND SANITARY OFFICERS.

To the Editors of THE LANCET.

SIRS,—Dr. J. H. Garrett, in his most excellent criticism on the administration of the Public Health Acts which appeared in THE LANCET of May 25th, p. 1447, has omitted to draw attention to what one may term the crowning absurdity of the law with regard to the appointment of medical officers of health. Dr. Garrett states that the law requires the medical officer of health to be a "registered medical practitioner *invariably.*" This is not strictly correct. The Local Government Act, 1888, requires that he shall be legally qualified to practise medicine, surgery, and midwifery, but by the same Act authority is specially given to the Local Government Board to modify this requirement—that is to say, the Local Government Board has power to sanction the appointment of a "quack." I am, Sirs, yours faithfully,

R. BRUCE FERGUSON, M.D. Cantab., D.P.H., &c.

London, N., May 27th, 1907.

ALBUMINOUS BODIES PRESENT IN PATHOLOGICAL EFFUSIONS.

To the Editors of THE LANCET.

SIRS,—Many thanks are due to Dr. W. C. Bosanquet's note on the above subject. I have been studying exudates and transudates from the same point of view during the past twelvemonth, but have adopted the plan of rendering the globulin precipitates free from salt by dialysis. I have supposed that globulin plus ammonium sulphate will keep unaltered for a long time and if that were the case this method would be devoid of the error against which we are warned. If the fluid to be examined be treated with the salt at once (as is possible in a hospital) need one fear any subsequent conversion of one globulin into another? These methods of analysis are naturally of no use clinically because it is a matter of days before the result is obtained, but as a subject of scientific research may we not still hope that the relative proportions of albumins, globulins, and the decomposition-products of proteids in these fluids are of profound interest?

I am, Sirs, yours faithfully,

OSKAR C. GRUNER, M.B. Lond.

Clinical Laboratory, Leeds General Infirmary, May 21st, 1907.

A SOCIETY FOR THE PREVENTION OF VENEREAL DISEASE.

To the Editors of THE LANCET.

SIRS,—Some years ago the medical profession in Germany formed a Society for the Prevention of Venereal Disease and last month was held the first meeting of a similar society for Austria. Is it not possible to do something of the same sort in Great Britain? Perhaps some of our leading medical men might make a start in the matter, as everything has to have a small beginning, and the three societies might work together in harmony and find some coöperation possible.

I am, Sirs, yours faithfully,

May 27th, 1907. H. N. R.

TRAINED NURSES ANNUITY FUND.—A drawing-room meeting will be held, by permission of Lord and Lady Ravensworth, at 71, Eaton-square, S.W., on Friday, June 14th, at 3.45 P.M., in furtherance of the objects of the annuity fund for disabled nurses. The Earl of Hardwicke will take the chair and the meeting will be addressed by Lord Loch, Lady Henry Somerset, and Dr. F. H. Champneys. Further information can be obtained from the honorary secretary, Dr. A. Ogier Ward, 73, Cheapside, London, E.C.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7471 births and 4578 deaths were registered during the week ending May 25th. The annual rate of mortality, which had been equal to 15·9, 15·7, and 15·1 per 1000 in the three preceding weeks, further declined to 14·9 in the week under notice. During the first eight weeks of the current quarter the death-rate in these towns averaged 16·2 per 1000, the rate during the same period in London being 15·8. The lowest annual death-rates in the 76 towns during the week were 7·5 in Hornsey, 7·8 in Smethwick, 8·1 in Tottenham, 8·7 in Willesden, and 8·8 in East Ham; the rates in the other towns ranged upwards to 20·1 in Stockport, 22·7 in Sunderland, 23·9 in Oldham, and 24·8 in Hanley. The 4578 deaths in the 76 towns showed a decrease of 52 from the number in the preceding weeks, and included 474 which were referred to the principal epidemic diseases, against 493 and 607 in the two previous weeks; of these, 207 resulted from measles, 116 from whooping-cough, 51 from diarrhœa, 46 from diphtheria, 35 from scarlet fever, 18 from "fever" (principally enteric), and one from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 1·5 per 1000, the rate from the same diseases in London being 1·4. No death from any of these epidemic diseases was registered last week in Plymouth, Halifax, Stockport, Devonport, or in six other of the 76 towns; the annual death rates therefrom, however, ranged upwards to 3·3 in Portsmouth and in Walsall, 4·1 in Middlesbrough, 5·0 in Derby, 6·8 in Bolton, and 7·0 in Hanley. The 207 fatal cases of measles showed a slight decline from the high numbers in recent weeks; the highest death rates from this cause were 2·1 in Derby, 2·6 in Middlesbrough, 2·7 in Bury, 2·8 in Nottingham, 5·1 in Bolton, and 7·0 in Hanley. The deaths from whooping-cough, which had been 176, 163, and 144 in the three preceding weeks, further fell last week to 116, and caused death-rates ranging upwards to 1·1 in St. Helens and in Swansea, 1·2 in Hornsey, 1·3 in Norwich, and 1·8 in Preston. The fatal cases of diphtheria, which had declined from 59 to 41 in the three preceding weeks, rose again to 46 last week, and included five deaths, equal to an annual rate of 2·1 in Derby. Of the 35 deaths from scarlet fever 13 occurred in London and three each in West Ham, Leicester, Liverpool, and Manchester. One fatal case of small-pox was registered in Cardiff, but none in any other of the 76 towns; and no small-pox patients were under treatment at the end of the week in the Metropolitan Asylums Hospitals. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2672, 2658, and 2679 at the end of the three preceding weeks, had further risen to 2732 at the end of the week under notice; 382 new cases were admitted during the week, against 348, 349, and 363 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 282, 262, and 235 in the three preceding weeks, further decreased to 230 last week, but were 17 in excess of the corrected average in the corresponding week of the previous five years. The causes of 46, or 1·0 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Newcastle-on-Tyne, Hull, Nottingham, Salford, and in 49 other of the 76 towns; the proportion of uncertified deaths, however, again showed a marked excess in Liverpool, Birmingham, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·3 and 19·7 per 1000 in the two preceding weeks, declined again to 17·5 in the week ending May 25th, but exceeded the rate in the 76 English towns by 2·6. The rates in the eight Scotch towns ranged from 12·9 in Paisley and 13·4 in Aberdeen to 19·8 in Greenock and 21·0 in Perth. The 607 deaths in the eight towns showed a decrease of 78 from the number in the previous week, and included 92 which were referred to the principal epidemic diseases, against 106, 110, and 112 in the three preceding weeks. These 92 deaths were equal to an annual rate of 2 6 per 1000, which exceeded by 1·1 the rate from the same diseases in the 76 English towns; they included 39 which were referred to whooping-cough, 28 to "fever," nine to measles, nine to diarrhœa, four to diphtheria, and three to scarlet fever, but not any to small-pox. The deaths referred to whooping-cough, which had been 40 and 52 in the two preceding weeks, declined again last week to 39, of which 33 occurred in Glasgow, two in Edinburgh, two in Dundee, and two in Paisley. The 28 fatal cases of "fever," all of which were attributed to cerebro-spinal meningitis, showed a decrease of 13 from the number in the preceding week, and included 19 in Glasgow, five in Leith, and two in Dundee. The deaths from measles, which had been 12 and eight in the two preceding weeks, rose again last week to nine, of which four were registered in Glasgow and four in Edinburgh. The nine fatal cases of diarrhœa included five in Dundee and three in Glasgow; the fours deaths from diphtheria occurred in Edinburgh; and two of the three deaths from scarlet fever in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 107 in each of the two preceding weeks, decreased to 83 in the week under notice, and were 13 below the number in the corresponding week of last year. The causes of 15, or 2·5 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; the proportion of uncertified deaths in the 76 English towns during the same week did not exceed 1·0 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 24·0 and 26·7 per 1000 in the two preceding weeks, declined again to 25·8 in the week ending May 25th. During the first eight weeks of the current quarter the death-rate has averaged 27·3 per 1000; the mean rate during the same period did not exceed 15·8 in London and 17·7 in Edinburgh. The 193 deaths of Dublin residents registered during the week under notice showed a decline of seven from the number returned in the previous week, and included 17 which were referred to the principal epidemic diseases, against numbers decreasing from 29 to seven in the four preceding weeks; of these, 10 resulted from whooping-cough, six from measles, and one from "fever." These 17 deaths were equal to an annual rate of 2·3 per 1000, the rate during the same week from the principal epidemic diseases being 1·4 in London and 1·8 in Edinburgh. The fatal cases of whooping-cough, which had declined from 15 to four in the four preceding weeks, rose again to ten last week; while the deaths from measles, which had been three, six, and one in the three previous weeks, again increased to six. The 193 deaths from all causes included 29 of children under one year and 45 of persons aged upwards of 60 years, each of these numbers showing a decline from those returned in the previous week. Six inquest cases and four deaths from violence were registered; and 98, or more than one-half of the deaths, occurred in public institutions. The causes of three, or 1·5 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths during the week did not exceed 0·2 in London, while it was 3·7 in Edinburgh. The 164 deaths registered in Belfast during the week under notice included 20 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon: J. C. Fergusson to the *Ariadne* on recommissioning; Staff Surgeon: S. T. Reid to the *Antrim* on recommissioning; Surgeons: W. H. Hastings to the *Antrim*, and A. R. Thomas to the *Ariadne* on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Major David Stiell retires on retired pay (dated May 25th, 1907).

Lieutenant-Colonel James S. Green is placed on temporary half-pay on account of ill-health (dated May 22nd, 1907).

Captain A. O. Duffey has been appointed to the Dublin District. Major T. B. Beach has been appointed Medical Officer, Royal Arsenal, Woolwich.

VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force :—

Northern Command: Rifle: 5th Volunteer Battalion the Durham Light Infantry: Surgeon-Major Andrew Arthur Abraham.

Scottish Command: Artillery: 1st Fifeshire Royal Garrison Artillery (Volunteers): Surgeon-Major Robert Balfour Graham. *Rifle:* 5th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant-Colonel James Mill.

THE ROYAL NAVAL HOSPITAL, STONEHOUSE, PLYMOUTH.

Inspector-General H. Mackay Ellis, Director-General of the Royal Navy Medical Service, made his annual inspection of the Royal Naval Hospital, Stonehouse, on May 21st and 22nd. After the inspection of the medical and surgical wards he expressed his satisfaction with the result of the visit. The Director-General was accompanied by Inspector-General H. T. Cox, R.N., and the heads of departments.

"Audi alteram partem."

MELÆNA NEONATORUM.

To the Editors of THE LANCET.

SIRS, -In your annotation on the above subject in THE LANCET of May 25th, p. 1443, it is suggested that melæna neonatorum may "be one of the many pathological conditions produced by the virus of congenital syphilis." This statement is supported by the authority of Dr. Balzer of the St. Louis Hospital, Paris, who states in his article on Syphilis in Brouardel and Gilbert's "Traité de Médecine," 1906, that some newly born children succumb to intestinal hæmorrhage associated with purpura, a condition known as "syphilis hæmorrhagica neonatorum." Dr. Still in his lectures on "Infantile Syphilis" also refers to this condition. Whether melæna neonatorum is always due to congenital syphilis may be open to dispute, but this diathesis is probably responsible for most cases.

I am, Sirs, yours faithfully,

New Cavendish-street, W., May 26th, 1907. C. F. MARSHALL.

CONVALESCENT HOME OF ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

To the Editors of THE LANCET.

SIRS,—May we ask you for space to appeal to Cambridge men and their friends for help in providing Addenbrooke's Hospital with a seaside branch for convalescents, such as is now felt to be a necessary equipment for every great hospital? These seaside branches are quite distinct from the ordinary convalescent home to which admission may be obtained through subscribers' letters for people needing merely rest and change of air. They are intended precisely for those whom such homes must of necessity exclude—viz., those who still need surgical care and dressings, including men, women, and children from three years old. The patients are nominated by the hospital staff and have all been under treatment at the hospital. There are thus no trivial cases. The removal of these patients at the earliest possible moment after operations or other severe illness gives much needed relief to the hospital wards, while the bright seaside and open-air life completes the work of restoration as nothing else could.

In response to an appeal made eight years ago by the medical and surgical staff of Addenbrooke's Hospital for such a branch the work was begun in a hired house by the seaside. The generosity of a few friends provided funds enough to try the experiment for some years and its success has been even beyond their hopes. But these funds are now exhausted; the lease of the temporary home at Dovercourt has come to an end; the committee has decided to build (no house not planned for this object being really suitable) and has secured an admirable site at Hunstanton. All that is now needed is £3000, towards which £600 have already been given or promised. Donations will be gratefully received at Barclay's Bank, Cambridge.

We are, Sirs, yours faithfully,
L. DE BUNSEN,
Honorary Treasurer of the Home;
DONALD MACALISTER.
Consulting Physician to Addenbrooke's Hospital.

Cambridge, May 18th, 1907.

SANITARY AUTHORITIES AND SANITARY OFFICERS.

To the Editors of THE LANCET.

SIRS,—Dr. J. H. Garrett, in his most excellent criticism on the administration of the Public Health Acts which appeared in THE LANCET of May 25th, p. 1447, has omitted to draw attention to what one may term the crowning absurdity of the law with regard to the appointment of medical officers of health. Dr. Garrett states that the law requires the medical officer of health to be a "registered medical practitioner *invariably*." This is not strictly correct. The Local Government Act, 1888, requires that he shall be legally qualified to practise medicine, surgery, and midwifery, but by the same Act authority is specially given to the Local Government Board to modify this requirement—that is to say, the Local Government Board has power to sanction the appointment of a "quack."

THE BATTLE OF THE CLUBS.

THE STRUGGLE AGAINST THE COVENTRY DISPENSARY.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1458.)

Coventry, May 27th.

THE dispute in regard to the Coventry Dispensary is a somewhat dramatic illustration of the inextricable tangle into which contract work has fallen. *As for the cause of the* embarrassment, it is easier to define than to remedy. It can be expressed in one word—commercialism. The practice of medicine has always been described as a professional pursuit. Money-making is therefore not the object, though it is a necessary corollary. In spite of the fact that modern economic developments have greatly reduced the rate of interest and menace the small capitalists, still the aspirations, the principles, and the etiquette governing the medical profession remain what they used to be. Indeed, the formation of medical unions throughout the length and breadth of the land will tend to strengthen and to enforce more strictly the ethical code by which the dignity of the profession is to be maintained. It is probable that if the sum total of capital necessary for a medical education together with an equal amount of work and ability were devoted to a trade or industry, the profit in hard cash made would, as a rule, far exceed that received in the form of fees for medical attendance. Therefore, if money is the primary object, trade, commerce, and industry suggest themselves and not the medical profession. To make this quite clear, the profession condemns as infamous, in the professional sense, practices which are quite legitimate in trade and commerce. As the desire to relieve suffering and to study science are the primary objects of the medical profession, its members have always been willing to do a great deal of gratuitous work. Such gratuitous work, notably that performed by the staff of the various hospitals, provides the means to relieve much suffering and to acquire great experience in the pursuit of scientific clinical study. Unfortunately, an unfair advantage has been taken of this somewhat altruistic and chivalrous attitude of the medical profession. This has reacted upon not a few medical men themselves and caused them, in a measure, to abandon their own higher standard of ethics. Thus a vicious circle has been created, those who were sinned against becoming in their turn sinners.

This situation *forced itself* more prominently than usual to my notice when I read carefully the defence made by the authorised representatives of the Coventry Provident Dispensary. This is set out at great length in the *Coventry Herald* of March 22nd last. A meeting of members of the dispensary is described which was presided over by Mr. A. Keene, chairman of the dispensary committee. In his opening *remarks* the chairman is reported to have said that "the all-important question is whether those who find the money shall rule or whether the medical staff shall likewise have a control of the management." The attitude of the members fully confirmed the chairman's assumption that they and not the medical officers found the money. Here, of course, is the fundamental error, the belief that because the members of the dispensary pay 3*s.* or 4*s.*, or at most 1*d.* per week, which makes 4*s.* 4*d.* a year, therefore the medical officers are fully paid for their services. The fatal mistake on the part of the medical profession is that they have not insisted throughout on the charitable nature of the work which they were doing. This argument applies, unfortunately, not only to Coventry but to the greater part of club practice or contract work throughout the country.

The origin of such dispensaries, sick clubs, &c., *must* always be borne in mind. If it had never been forgotten, the cause for the present protracted battle of the clubs would not have arisen. At the commencement of the last century medical men gave their services gratuitously at the hospitals and also to a large number of poor people who rarely, if ever, were able to pay. Then in the "forties" a great humanitarian spirit of reform swept over Europe and all kinds of organisations were set on foot for the benefit of the poor. The Coventry Dispensary was a pioneer in this effort, for it was first started in 1832. Its original character as a charitable institution I have already fully described, quoting notably a resolution which was carried on July 29th, 1829, in St. Mary's Hall, Coventry, and which was to the following effect:—

> 1. That this meeting of the medical men of Coventry regrets, after a full consideration of the subject, that they cannot approve of the establishment of a self-supporting dispensary in this city, the principles of which they think are not adapted to the locality of Coventry. 2. That this meeting would most cordially coöperate with their fellow citizens in establishing a charitable dispensary upon the usual terms of such institutions.

Even at this early date the members of the profession foresaw the danger of what was called a self-supporting institution. It was the opposition of the medical men that caused some three years or more to elapse before the dispensary could be established; and though often stated to be self-supporting it has remained throughout a charity. All attainable statistics clearly demonstrate this to be the case. In April, 1893, a great meeting of the members of the Coventry Dispensary was held and the mayor, who was in the chair, boasted that the dispensary had in hand a balance of from £5000 to £6000. This money had been bequeathed to the "Benevolent and Provident Dispensary." Surely such bequests cannot be considered in any other light than as charitable donations, they were not investments. In those days the dispensary did not fear to publish statistics, and speaking of the abuse of the institution by rich men a prominent member, Mr. J. Bill, who at one time was chairman of the institution, said it was absurd to urge that a man who "could pay 5*s.* or 2*s.* 6*d.* but chose to pay only 2*d.* or 3*d.* for a doctor's visit was a man of honour." Here, then, we have on the highest authority *and from the dispensary* side a statement given when the figures were published that the medical officers of the dispensary only received 2*d.* or 3*d.* for each patient whom they saw. Surely this is charity, not in cash certainly, but in kind.

To-day the figures, the statistics, are carefully concealed. The dispensary management is so well aware it is in *the wrong that it* dare not publish a record of what it does. It no longer issues the annual report that it was in the habit of publishing; indeed, the dispensary even pretends that it does not know how many members it possesses. Though it collects the weekly pennies or the annual subscriptions, yet it cannot say how many members are paying. When the population of Coventry was less than 60,000 the dispensary boasted of 26,000 members. Now that the population is estimated at *87,000 the dispensary pretends* that it has less than 20,000 members. The managers publish details as to the payments made to their medical officers but they will not state the number of consultations given in exchange for these sums or the extent of the population placed under the charge of the medical officers. The latter do not themselves know. Perhaps for the *purpose* of keeping the medical officers and the public in ignorance of the true state of affairs, a different system of payment has been introduced. As a rule a medical officer of a club or dispensary has inscribed in his book the names of all the members who have selected him for their attendant should they require medical aid. The medical officer is paid in proportion to the number of *members* on his book. If it is a healthy and young population the work is comparatively slight, though *often the conditions* are not so favourable. At Coventry the medical officers have no such books. They are paid by result and not by membership. Every weekday morning and on one evening—that is in all seven times per week—the medical officers go to the dispensary building and there receive all members who choose to ask their advice. It is like the out-patients' ward at a general hospital. There is a bookkeeper and he enters to the credit of each medical officer the patient by whom he is selected. This account is made every six months. At the end of six months if a patient continues his visits he is entered as a new patient but he can call as often as he chooses during the six months. Thus Dr. T. A. Hird, who has the largest number of dispensary patients, said he expected to find some 4000 entries made for the last six months of his services. *That is to say,* he will have given advice to 4000 different persons during the six months, seeing some of them only once and others several times according to the nature of their complaints. As he receives about a third of the total amount paid to the medical officers the population that looked to him in case of sickness probably have numbered from *6000 to 8000* persons.

Though official figures are not attainable an approximate estimate amply suffices for all practical purposes. In this respect I have fortunately been able to obtain from the best-informed source the statement that the more popular members of the staff may have to see at the *dispensary* from 60 to 130 patients, and in addition have *to visit* about 30 at their own homes. This may mean therefore *160* visits and consultations per day. However such figures are interpreted they show the unsatisfactory state of affairs. For instance, I will make a fancy calculation and so as to avoid the accusation of overestimating the grievance I will take as a basis not 160 but only 100 visits and consultations per day and only 310 days of such work per annum. This makes 31,000 visits and consultations. Suppose we accept as the lowest minimum fee 1*s.* 6*d.* a consultation and 2*s.* 6*d.* a visit at the patient's own house, but as the dispensary medical officers do not provide the medicine I will set down the visits at the same fee as the consultations. The medical officer who sees on an average 100 patients per day for 310 days in the year should, at the rate of the minimum fee of 1*s.* 6*d.*, receive £2325. The highest sum ever paid to any one medical officer at Coventry was, according to the printed statement, £843 15*s.* 4*d.* for the year 1906. From the above figures, and to judge from all appearances, the probability is that this payment, though large, represents less than 6*d.* per visit or consultation. If the dispensary was a self-supporting institution where it actually pays a little more than £800 it should pay a great deal more than £2000.

There is, however, the other side of the question. If a medical practitioner received what is recognised as a full and proper fee, even though this be but the minimum fee, then the patient may expect the best treatment that it is in the power of his medical attendant to give. The ideal would be that when once at work the question of fees should not enter the practitioner's mind. It should never occur to him to say, "This is only a club patient, I cannot afford the time to examine him thoroughly." How long a consultation should last on an average has never been clearly defined, though there is a tradition about the professional quarter of an hour. Certainly this might be cut down without injury, and in dealing with a poorer class of patient the practitioner might be allowed to come to the point at once without loss of time over preliminary politeness. Therefore, and for the sake of argument, perhaps I may venture to suggest an average of ten minutes per patient. If in this is included the time taken in going to the different houses of those patients who cannot come and wait their turn at the dispensary or the surgery ten minutes per patient is a short allowance. But if this basis be accepted then in order to see 100 patients in a day the medical officer would have to devote 16 hours and 40 minutes. Under these conditions the medical officer would then have 7 hours and 20 minutes remaining for his other and better paying patients, for study, for his relaxation and pleasure, for his meals, and last, but not least, for sleep. If, however, he had, as stated above, 160 patients to see he would require more than 26 hours; therefore it could not be done, even if he worked all day and all night without a moment's pause for any purpose whatsoever. These figures show how both sides, the dispensary and the medical staff, have drifted into a false position.

The great difficulty in discussing the matter is the absence of an official pronouncement as to what should constitute the minimum fee. From numerous conversations all over the country 1*s.* 6*d.* and 2*s.* 6*d.* seem to be considered the lowest fees likely to be accepted if a plébiscite of the profession could be taken. With this understanding and to facilitate calculations we might adopt as an average 2*s.* for visits and consultations when medicine is provided and 1*s.* 6*d.* when the medical officer does not give the medicine. On the other hand, the minimum fee should be not for the minimum of attendance but for the full measure of what is necessary and this I have very roughly estimated at an average of ten minutes per patient. The difference between the sum paid to the medical officer and the 1*s.* 6*d.* which he should receive ought to be credited to his account and considered as a free gift made by him to the institution. It would then very soon be evident that these dispensaries and similar institutions are not self-supporting. They are charitable institutions and far and away the largest amount of charity given has been contributed by the members of the medical staffs.

The case on the side of the medical officers would be very clear and very startling if unfortunately almost irresistible economic forces had not compelled them to retaliate. Both sides have been to blame, the medical officers because they did not insist on the charitable nature of the work which they were doing and the members because they too readily imagined that they were paying for the services of the medical men; just as if such service, if properly rendered, could possibly be paid for by subscribing a penny per week. Not only did many of these institutions conclude that they are fully paying their medical officers but they often assumed an over-bearing tone, as from a master to a dependent. One of the Coventry dispensary officers remarked that if he went to a shop and bought something he did not treat the shop-keeper as if he was an unruly servant. He considered his relations with a tradesman as those of mutual service, but it often happened that the members of the dispensary were not so courteous or so considerate. In course of time and meeting with but little gratitude, the tendency to make the best of a bad situation naturally arose. As the charitable element became obliterated so did the commercial instinct manifest itself even among the members of the profession. Thus the professional ten minutes gradually dwindled and the time allotted to the patients became more and more proportionate with the commercial value of the pennies which they paid. It was not because medical men were insufficiently paid—that was but a secondary consideration—but it was because the practice of medicine was being degraded by an infusion of a low class of commercialism that the battle of the clubs was commenced.

Among the early pioneers of this movement were the majority of the Coventry medical practitioners. How they denounced the Coventry Provident Dispensary and formed a Coventry Public Medical Service managed solely by members of the profession has been fully described in these columns and the progress made recorded from time to time. The dispensary constituted a huge monopoly, handing over a population of some 25,000 persons to five medical men who would thus have many thousand more people on their books than they could possibly attend to properly. Therefore, when the medical practitioners of the town set themselves to the task of organising a model medical service for those who were too poor to pay the usual fees, they declared that there should be no monopoly but that every recognised resident practitioner could join if he chose to do that sort of work. Then, and so as to prevent any practitioner undertaking more than he could properly accomplish, there was a self-denying ordinance limiting to 2000 the number of members whom any one medical officer could inscribe on his books. To prevent the abuse that was so largely prevalent at the dispensary a wage-limit of £1 10*s.* per week was imposed and no one was admitted as a member whose income exceeded this sum. The Public Medical Service has continued to prosper. Last year 2800 new members joined while 1840 lapsed, leaving a net increase of 960, which brings the total membership up to 12,572. The total amount of money collected was £2588; of this £581 were paid to the dispensing chemists, £305 to the collectors, and £1603 were divided between the ten medical officers who do the work of this institution. This is equal in round figures to 2*s.* 6*d.* net per annum and per member after the cost of management, of drugs, and of collecting has been paid. At this rate 2000 members would bring in a net income of £250 a year, and this is very generally considered quite as much club practice as any one practitioner should undertake if it is to be done properly and if sufficient time is left for practice among patients who can afford to pay the usual fees, for study, and for relaxation.

This self-denying ordinance, this limiting of club patients to 2000, is entirely in the interests of the public, and especially of the poor. Nothing can be more disastrous to the poor than that a medical practitioner should make the greater part of his income out of club practice. The calculations and figures given above show what this means, and, indeed, the poor themselves so well understand the question that the phrase "only a club doctor" is quite current among them. Therefore, when serious illness arises they endeavour to get money enough to consult a practitioner who is not a club doctor. It would be a great advantage to the sick poor if their club doctor derived the greater part of his income from patients who paid the full fees, for he would then be much better able to afford all the time necessary to take equally good care of his club patients. This also would better guarantee the dignity and honour of the profession, and hence the present struggle.

Unfortunately the members of the profession at Coventry have recently gone back upon some of their old and excellent resolutions. The spirit of compromise has been permeating their ranks, and for the sake of being practical they have forsworn some of their best principles. As a few practitioners in the neighbourhood had private clubs of their own with more than 2000 members, a resolution was carried raising the limit of members on any one practitioner's book to 3000. Then the other day, and in the hope that the five medical officers of the dispensary who have resigned would join, the self-denying ordinance was abolished altogether. Thus the rule which constitutes the chief claim of the Coventry Public Medical Service to the support and sympathy of the general public has been abolished. There would have been some excuse for this if by so doing the medical officers who have given up the dispensary could have been induced to join; but this they will not do. They are going to run private clubs of their own and they think that their patients will leave the dispensary to follow them. Apart from this question of the popularity of the individual medical men, the patients will enjoy some advantages which they did not have at the dispensary. The medical officers are making arrangements to receive their patients at their own private surgeries, so there will not be the same crowding that occurs at the dispensary building where all the staff receive the patients. Then, instead of being able to see a given medical officer in the evening only on one day per week, preparations to receive their patients during five evenings in the week as well as every morning have been made by the medical officers who have resigned. As obviously some members will not leave the dispensary the five medical officers who have resigned will lose some of their patients. Therefore they will give longer hours for consultation to fewer patients. There is no denying that this will be a great improvement from the point of view of medical science on the one hand and of the patients on the other. But such is the vicious tangle into which the system has become involved that this improvement will not be effected without imposing on the medical officers concerned a considerable financial loss. The best chance of recoupment is that there will be less abuse and that some of the well-to-do members of the dispensary will now pay the usual fees.

If the facts of the case can be made known to the public at large the dispensary will be abandoned or radically reformed. The three newly appointed and imported medical officers will find themselves in a difficult position. At Coventry and at Birmingham the profession is absolutely united against them and their ostracism will be thorough and effective. Though the dispensary officers who have resigned had drifted, as explained above, into a false position all criticisms in regard to the past are in abeyance. An absolutely united front is presented to the common enemy. All the practitioners of Coventry have promised not to accept as club patients any member of the dispensary, so that these members must follow the medical officers who resigned or remain in the dispensary. By this means it is hoped that the loss of the officers who resigned will not be so great. This self-denying ordinance will last for 12 months so far as individuals are concerned and for two years in regard to the clubs that are affiliated to the dispensary. It cannot be said, therefore, that the practitioners of Coventry have urged a rupture with the dispensary in the hope of picking up some crumbs. Of course the hospital staff will have nothing to do with the dispensary and its imported medical staff and the same may be said with regard to the *personnel* of the Birmingham hospitals. When it was necessary to remove a dispensary patient to a hospital the dispensary medical officers, being on personally friendly terms with the staffs of the Coventry and Birmingham hospitals, could telephone and make arrangements for their patients. This is not possible now, for no communications will be held with the new dispensary medical staff. The dispensary patients must themselves negotiate with the hospitals; their medical attendants, if they belong to the dispensary staff, cannot help them. Such is the nature of the fight which will begin next quarter day when the five medical officers who have resigned will leave the dispensary and the three imported medical officers will take their places.

THE GERMAN SURGICAL CONGRESS.[1]

(FROM OUR BERLIN CORRESPONDENT.)

(Concluded from p. 1382.)

Treatment of Fractures of the Femur.

Professor **BARDENHEUER** (Cologne) said that in the treatment of fractures of the femur the obtaining of results which were satisfactory from the anatomical point of view was the best security for the future serviceableness of the limb. It might be concluded from the position of the fragments in a recent fracture whether a displacement was likely to occur and whether this might be avoided by prophylactic measures. In fractures of the diaphysis where the angle opened inwards the flexure became greater in course of time when the femur was subjected to much weight before the completion of ossification. On this account after a certain period the limb became shorter than it was immediately after the end of the treatment. The deformity must therefore be remedied as well as possible in the anatomical sense and the patient should not be allowed to leave his bed before three months. The prognosis of displacement where the angle of the fracture opened outwards was better and the case was the same in displacements in the longitudinal direction where subsequent shortening of the bones was less likely to occur. Professor Bardenheuer had devised an elaborate system of making traction in every case of fracture. When the fragments were displaced with an angle opening inwards he applied, in addition to the usual traction in the longitudinal axis, three other tractions—namely, one towards the middle line of the body, one at the place of the fracture, and a traction on each fragment towards the exterior. When the displacement was very great so that the fragments did not touch each other at all the traction must be made with a weight of 70 pounds. In 159 cases which Professor Bardenheuer treated in this way there was no shortening. In subtrochanteric fractures where the upper fragment was much flexed simple extension was not sufficient but downward traction made through a hole in the mattress must also be applied. In supracondylar fracture not only must extension be made in the longitudinal axis but upward traction must also be applied to the lower fragment and outward traction to the upper fragment. With regard to fractures of the neck of the femur Professor Bardenheuer has observed 14 different varieties for each of which a separate method of traction had to be applied.

Professor **KÖNIG** (Altona) discussed the indications for wiring the broken ends of the femur. Fractures of the diaphysis were, in his opinion, not suitable for the operation, except in the case where portions of muscles were interposed between the ends of the bone. The proper cases for wiring were fractures of the neck of the femur; it had been found post mortem that even impacted fractures of the neck where the upper fragment had entered the trochanter had become united by fibrous tissue only. This fact explained the shortening of the limb when the patient began to walk. The same was the case in intracapsular fracture, in which also a fibrous union only took place. He therefore recommended wiring in cases of fracture of the neck of the femur. He said that this fracture was not, as was commonly believed, peculiar to advanced life, but might occur in middle-aged persons and even in children. He alluded to the case of a tuberculous patient in whom a fracture had been wired and who died some months afterwards from pulmonary tuberculosis. It was found at the post-mortem examination that osseous union had taken place only on the anterior side where sutures had been applied but not on the other sides where only a fibrous union had taken place. Isolated fracture of the great trochanter was also an indication for wiring because of the liability to serious loss of function in the event of union being imperfect. As to subtrochanteric fractures, those which were transverse might be treated by simple traction, while for those which were oblique Degage's splints were the best treatment. Traction was also sufficient in supracondylar fracture, except when there was traumatic loosening of the epiphysis, as in these cases the diaphysis was displaced backwards and might lead to gangrene by compression of the popliteal vessels. As material for suture Professor König preferred aluminium bronze wire and recommended that the patients should keep their beds for ten or 12 weeks.

Professor **SCHLANGE** (Hanover) said that in fractures of the diaphysis of the femur he had sometimes made the fracture accessible by an operation and replaced the ends of the bones in proper position without wiring. The external wound was then sutured, the thigh was fixed in a plaster-of-Paris splint, and firm union without deformity was obtained.

Dr. **NIEHANS** (Berne) recommended that the ends of the bones should be temporarily fixed by pegs, which were subsequently removed under local anæsthesia by cocaine. This proceeding was especially valuable for children whose restlessness was unfavourable to firm union taking place.

The Treatment of Enlarged Prostate.

Dr. **KÜMMELL** (Hamburg) said that in his opinion complete enucleation of the gland was preferable to partial extirpation. With regard to the time when an operation should be performed he said that it was not necessary in the first stage but only when residual urine was left notwithstanding catheterisation, and especially when cystitis or hæmorrhage had set in. An operation was contra-indicated in arterio-sclerosis, in renal insufficiency, in Bright's disease, and when the bladder had completely lost its contractility. The mortality after the operation was 10 per cent. Suprapubic cystotomy was as a rule preferable because it allowed a better view of the bladder for the detection of diverticula and calculi. It did not lead to fistula, to impaired control of the bladder, or to impotence, all of which were frequent sequelæ of perineal operations. The perineal operation was advisable only in cases of extreme obesity and prominence of the rectum. Among 41 operations performed by him there were nine in which cancer was present and the mortality of these was 33·3 per cent. After the operation micturition was under the patient's control and the urine could be retained for a period of from four to six hours. Strictures, however, sometimes developed subsequently. The operations were performed under spinal anæsthesia obtained by Professor Bier's method. When the bladder had been opened the prostate was pressed forward by a finger introduced into the rectum and a circular incision was made round the entrance of the urethra; the gland was then enucleated, the prostatic portion of the urethra being preserved as much as possible. When the bladder was not infected the mucosa and the walls of the bladder were sutured, the abdomen was closed, and a catheter was tied in.

---

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medizinische Wochenschrift*, through whose courtesy it has been forwarded to us by our Berlin correspondent.

Professor RYDYGIER (Lemberg) advocated an early operation. He said that he had always performed a perineal operation without opening the urethra. He made an incision on both sides of the capsule and then enucleated the gland, preserving, however, two long strips of prostatic tissue about one centimetre thick at the external side of the urethra. He had never found that his operations resulted in either fistula or impotence and his patients were able to leave their beds on the second or third day.

Professor ISRAEL (Berlin) said that owing to the high mortality of the operation he only performed it when the patients were no longer relieved by catheterisation. He had always used the suprapubic operation even in very fat persons. As he had once seen profuse secondary hæmorrhage occurring after the lapse of a fortnight he always introduced a drainage-tube and left the wound of the bladder open.

Professor ROVSING (Copenhagen) recommended a more conservative proceeding. He opened the bladder only when there was profuse hæmorrhage or when there were calculi or when catheterisation was not possible; he only removed parts of the gland and was opposed to the total removal of it because serious mental aberration, leading even to suicide, had been found to occur after total removal. He had treated cases with complete success by vasectomy. In severe cystitis he made a small incision into the bladder, introducing a catheter, by which the bladder was irrigated with a solution of silver nitrate.

Dr. PAYR (Gratz) said that he had performed prostatectomy twice under local anæsthesia. Enucleation was very easy when the connective tissue was loosened by injection of the anæsthetic fluid between the capsule and the body of the prostate.

Cancer of the Bladder.

Professor ROVSING said that he had performed total removal of the bladder either when there were multiple deposits of cancer or when a considerable area of the wall of the bladder was attacked by the growth. Metastases in the lymphatic glands occurred rather late. In operating he made a curved incision through the skin and the muscles of the abdomen. The bladder, which was filled with 250 grammes of antiseptic fluid, was not opened, but was enucleated first on the anterior, then on the lateral, and finally on the posterior aspect. The ureters were divided two centimetres above their entrance into the bladder and were left hanging *externally* through two lumbar incisions.

Resection of the Liver.

Dr. ANSCHÜTZ (Breslau), in giving some account of the methods followed in resection of the liver, said that the hæmorrhage might be checked in various ways. In one style of operating the affected parts were quickly removed by free incisions; the bleeding surface was temporarily compressed by assistants and all the bleeding points were successively tied. Another plan was to make a preliminary application of ligatures in each region and then to cut the tissue slowly. It was essential to have a good view of the field of operation. He preferred temporary resection of the ribs to the transpleural method. Below the seventh rib the pleura was no longer met with if the incision was made on the cartilaginous part; below the tenth rib even the bone might be cut through. In resection of a wedge-shaped piece of the liver the cut surfaces that were left must be cautiously united by sutures, after which the abdominal wound was closed.

Abscess of the Spleen.

Professor KÜTTNER (Marburg) said that abscesses of the spleen might be caused by mechanical injury, by septic infection, or by infarcts in malaria, in enteric fever, in puerperal fever, and in ulcerative endocarditis; they might also be caused by direct contact in cases of perforation of the stomach. When it was found that subphrenic abscesses of the left side contained pieces of tissue among the pus it must be suspected that they proceeded from the spleen. Professor Küttner described a case in which the spleen had been removed on account of a gunshot wound and in which an examination made after the patient's recovery proved that the number of the red corpuscles had increased to 6,000,000 per cubic millimetre and that the hæmoglobin had increased to 129 per cent. He showed a patient suffering from myelogenic leukæmia whose spleen he had removed. It was moveable and enormously enlarged. No effect was produced on the leukæmia and no benefit was obtained from treatment by the x rays.

Gangrenous Hernia.

Dr. RINDFLEISCH (Stendal) said that in operating on gangrenous hernia he had used a method of invagination devised by himself. After detaching the mesentery from the gangrenous intestine the latter was compressed by Doyen forceps at the boundary between the gangrenous and the healthy parts and was then invaginated. The serosa of both parts was then united by sutures, after which the gangrenous portion was spontaneously thrown off.

Torsion of the Omentum.

Dr. ADLER (Pankow) reported a case of supposed appendicitis in a hernial sac which he had operated on. When the sac was opened omentum containing extravasated blood was found in it. Laparotomy was thereupon performed and showed that the omentum as far as the transverse colon had become twisted on itself so as to make a complete revolution. The omentum was removed and the patient recovered.

Meningitis Serosa Spinalis.

Professor KRAUSE (Berlin) said that among 20 patients who had presented symptoms suggesting spinal tumour and had been operated on by him he had eight times found within the spinal arachnoid circumscribed collections of fluid, which at the operation escaped in such a way as to show that it was under considerable pressure. These collections must have originated by inflammatory adhesions between the dura mater and the pia mater. The paresis of the limbs and the difficulties which had been experienced with the bladder and rectum disappeared after the operation. In Professor Krause's opinion these cases proved that meningitis serosa spinalis had a real existence.

Election of President.

Professor VON EISELSBERG (Vienna) was elected as President of the Congress at its next meeting.

FOOD AND THE HEALTH OF THE NATION.—The members of an association known as the Bread and Food Reform League have arranged to hold a meeting at the Mansion House on June 26th to inaugurate a campaign designed to spread—without advocating any special system of diet—scientific and practical information about healthy and economical foods. The prevention of adulteration will also be in their scheme for insuring that the nation may have well-fed, healthy children. The Lord Mayor, who will take the chair, is to be supported by, among others, the Marchioness of Ormonde, Sir James Crichton-Browne, Sir John Jardine, Sir Walter Vaughan Morgan, Sir William Ramsay, the Rev. Prebendary Carlile, Mr. A. Pearce-Gould, Dr. G. A. Heron, Mr. Mayo Robson, Sir William J. Collins, and Sir Alfred Fripp, and representatives of societies interested in promoting the welfare of the people. Tickets and further information may be obtained from Miss May Yates, honorary secretary, 42A, Bloomsbury-square, London, W.C.

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

V.[1]

THE CAMARAN LAZARET (*continued*).

The Three Water Services: (a) Sea-water Supply; (b) Fresh-water Supply—the Distilling Apparatus, Central and Peripheral Reservoirs, Mode of Distribution, and the Ice Machine; and (c) Well-water Supply.—The Two Existing Method of Excreta Disposal: (a) The Motte System—Latrines, "Collectors," Cesspools, Pumps, Excreta Tanks, and "Jetée de Vidange"; and (b) Latrine Jetties on the Sea-shore.—Defects of Both Systems.—New System Proposed.—Trough Closets with Automatic Flushing-tanks; "Fosses à Fond Perdu"; Experimental Observations.

THERE are three water services in the Camaran lazaret: (*a*) sea-water, (*b*) fresh-water, and (*c*) well-water. Each of these services has one or more systems of pipes, by which the water is distributed to different parts of the lazaret.

(*a*) *Sea-water service.*—Sea-water is distributed to all the cordons to supply the latrines, to the disinfecting pavilion for the baths, and also to the distilling apparatus and ice-machine. There are two separate sea-water services: one for the first, second, and third cordons, and the other for the fourth, fifth, and sixth cordons. Each has a powerful pump which raises the water to a large central reservoir. These reservoirs are placed at the top of water-towers; the water-tower for the three further cordons is seen in Fig. 5 (No. III.), whilst a similar, but lower, tower, near the machinery buildings, supplies the first three cordons. From the central reservoirs the water flows to smaller reservoirs on lower towers, one of which exists in each cordon. All the reservoirs are built of armoured cement; the pipes are of cast iron. In the cordons themselves smaller pipes of the same material distribute the water to the latrines. The two "central" reservoirs can hold respectively 20 and 19 tons of sea-water; those in the cordons can hold about ten tons each.

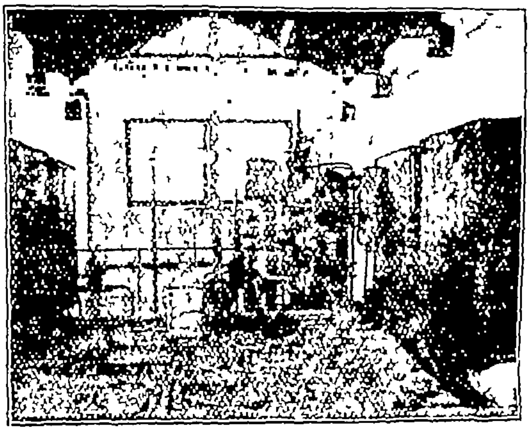
The concentration of the lazaret will involve the abandonment of the sea-water service for the three further cordons as it now is. The Commission proposes to put up one large central reservoir of 50 tons in place of the 20-ton reservoir near the administrative buildings which now serves for the first three cordons, and to have one system of piping for all the six cordons. Both pumps would be housed close by the new large reservoir. By taking up the pipes which cover the long distances between the three further cordons in their present positions, the lazaret will have something like two kilometres of piping in reserve. It is further recommended to provide all the reservoirs with ball-taps, permitting of their automatic filling, and with water gauges.

(*b*) *Fresh-water service.*—The drinking-water at Camaran is provided by a distilling apparatus, which converts sea water into excellent fresh water. The machine was bought from the firm of Mirrlees, Watson, and Yaryan of Glasgow in 1895. The total cost (including the distilling apparatus itself, transport, mounting, boilers, and other accessories) was about £4000. It has given excellent results. It produces about 26 tons of fresh water in a day of 12 hours; working day and night it can produce as much as 60 tons in the 24 hours. The amount of coal burnt varies with the quality; on an average a ton of water can be furnished by burning about 45 kilogrammes of good Cardiff coal, whereas of Indian, Newcastle, or Turkish coal it requires 60 kilogrammes to produce the same quantity of water.

Distilled water is given gratuitously to the pilgrims, to the staff of the lazaret, to the local postal and customs authorities, to the crews of the Turkish stationnaires, to the officers of the military guard at the lazaret, to all workmen or employees, to ships in quarantine (if asked for), to government transports, to the military hospital, and to the staff of the Camaran arsenal. It is also distributed to the ice machine, to the generators of all the machines, and to the disinfecting stoves; and finally, a certain amount is sold on the island or on the mainland. The price is 60 piastres (10*s.*) a ton. The quantity of distilled water allowed to each pilgrim is five litres a day, to each unmarried member of the staff ten litres, and to each married member 20 litres.

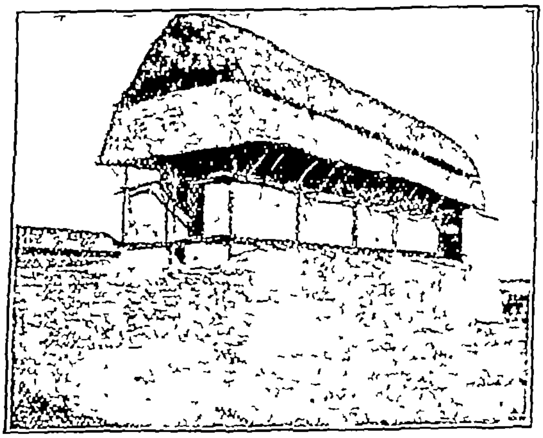
From the distiller the water passes to 16 large reservoirs, eight of which are in the machinery building itself (see Fig. 14) and the other eight are placed in the curious structure which appears in Fig. 15. The basis of this structure is of very solid masonry and was originally intended to store the ice made in the ice machine, to which I shall refer presently. As a matter of fact, ice is never stored there, as it is distributed as rapidly as it is prepared, but the whole structure is still often called the "*depôt de glace.*" The eight iron reservoirs, four small and four large, are supported on very thick masonry walls and are covered over with a roof of matting and palm-leaves, which protects the water from the sun's heat. The whole has rather a droll appearance but is none the less a very practical and successful arrangement.

FIG. 14.



Fresh water reservoirs in the machinery building.

FIG. 15



Fresh water reservoirs over ice depôt.

From the eight reservoirs in the machine building itself the water passes to a filter outside, below which is another small reservoir with tap attachment. From here a five-centimetre pipe conducts the water right to the end of the Mervani landing-stage, where portable tanks can be filled and the water thus conveyed to ships that require it. The water from these reservoirs is also distributed to the staff of the lazaret, to workmen and employees, and, in short, to all the persons other than pilgrims mentioned above. Some of it is even, under existing conditions, carried to the three further cordons of pilgrims; but that, as will be shown, was not originally intended to be the case and has been necessitated solely because the water does not flow freely to those cordons in the piping provided for it.

---

[1] Nos. I., II., III., and IV. were published in THE LANCET of April 27th (p. 1183), and May 4th (p. 1251), 11th (p. 1317), and 18th (p. 1359), 1907, respectively.

From the eight reservoirs over the so-called "ice depôt" two pipes conduct (or should conduct) the water to the six cordons for the use of the pilgrims. One is a pipe of five centimetres (about two inches) and distributes the water to cisterns in the first three cordons; the other is a pipe of six centimetres and is intended to distribute the water to the last three cordons. But for some reason that has not been satisfactorily explained the water has never reached these distant camps or has reached them in extremely small quantity. No doubt the long distance the water has to flow, and the fact that some of those camps are on rather high ground, increases the difficulty which the water finds in reaching them; but in the opinion of an engineer who accompanied the Commission there is a sufficient difference in level between the central and peripheral reservoirs to allow of a free flow, and he ascribes the difficulty to some serious obstruction of the pipes. He suggests that in all probability, when the pipes were first laid down, a careless workman in soldering them up allowed a quantity of lead to run into the interior at one or more joints and that this has caused the obstruction. The explanation is a very probable one and is supported by the fact that the obstruction has existed from the time the pipes were laid down. The only way to prove or to disprove the truth of this assumption would be to examine every joint, but as the Commission proposes in any case to do away with this second piping and have a single system of pipes for all six cordons the question ceases to be of practical interest, save as indicating the necessity of care in future and of supervision of the workmen employed to lead the joints.

In suppressing the second system of fresh-water pipes a vast quantity of these pipes (over five kilometres) will be set free; some will be needed for continuing the first system to the three further cordons and the rest can be employed to conduct water to the hospitals, to the houses (new and old) where the staff is lodged, and elsewhere.

In the camps themselves it was originally intended to stock water in large underground cement reservoirs, and such a reservoir was constructed in each cordon. They vary in size; some are large enough to hold 30 or 40 tons of water. But they have never been used as originally intended. Iron cisterns were ordered, and these have in many instances been placed inside the cement reservoirs. The Arab employee has to descend a flight of steps to the bottom of the underground reservoir and fill the pilgrims' water-jugs from a tap in the iron cistern. The arrangement is not a satisfactory one; the bottom of the reservoir is always damp and has often an unpleasant smell; there is little room between the walls of the reservoir and the cisterns; and the employee fills the pilgrims' receptacles in semi-darkness and away from all control by any higher functionary. For these reasons the Commission proposes to place the iron cisterns above ground in all the camps, in a position where the medical man in charge can control the operation and to cover the cisterns with a mat and palm-leaf roofing to protect them from the sun. This method has already been adopted in one of the cordons and has given excellent results.

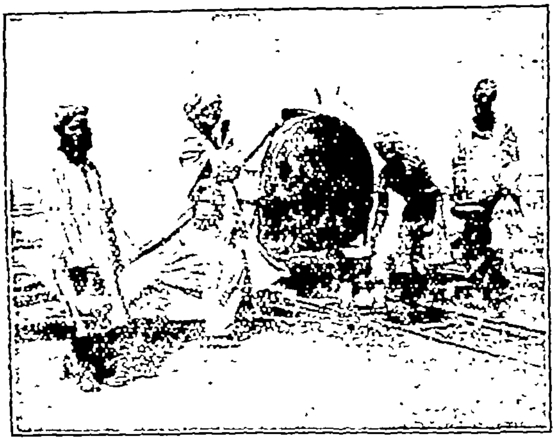
In the further cordons, as already stated, though the reservoirs exist, no (or little) water reaches them. Water is therefore carried in tanks on wheels, which are pushed by Arabs along the Décauville railway from the central reservoirs to the camps. This method involves much labour and expense; the water risks getting contaminated, and it becomes unpleasantly heated by the sun. One of these portable cisterns, under a tent, is seen in Fig. 16; the photograph was taken at the fourth cordon.

The Commission recommends that all the reservoirs, central and peripheral, should be provided with ball-taps and overflow pipes. By the side of most of these charcoal and sand filters already exist.

The water is distributed to the pilgrims twice a day—morning and evening. Each pilgrim receives a small metal tally, giving him the right to two and a half litres (rather more than half a gallon) twice daily. Before going on to describe the third system of water-supply (well-water) it will be convenient to mention the ice machine.

The ice machine.—This was bought from the firm of de Nayer, of Brussels, in 1896. It is installed in the same building as the distilling apparatus. It can produce 1200 kilogrammes of ice in 12 hours, or 3000 in 24 hours; ordinarily it works about 11 hours a day in the pilgrim season. The ice, which is of excellent quality, is given gratuitously to most, if not all, of the persons mentioned above as receiving free rations of distilled water. It requires about one and a third tons of coal to produce a ton of ice.

FIG. 16.



Moveable water tank under tent at the fourth cordon.

(*c*) *Well-water supply.*—In a very picturesque oasis in a valley lying to the north-west of the village of Camaran there are a score or more of wells of different sizes and depths. Seven of them supply a certain amount of water to the lazaret, while the rest furnish the village with their sole drinking-supply, and morning and evening a stream of camels and donkeys may be met, carrying the water in empty petroleum tins or in skins. The seven wells that furnish the lazaret have been at some time surrounded by walls and a rather elaborate arrangement of filters and reservoirs has been constructed in their neighbourhood. These have for the most part fallen in ruin. The enclosure round the wells nevertheless remains and a masonry tank, in which the water deposits some of its grosser impurities, is still in good condition. Some of the wells, the enclosure, and the tank are seen in Fig. 17. The tank is laboriously filled from the wells by Arabs who use for the purpose a primitive leather receptacle, as shown in the illustration. It is proposed to put up one or more pumps which will render the process easier and speedier. From the tank a five-centimetre pipe conducts the water down the valley to stand-pipes, situated near the brick-fields (to be mentioned later), which is the

FIG. 17.

The wells. Arab filling reservoir with well water.

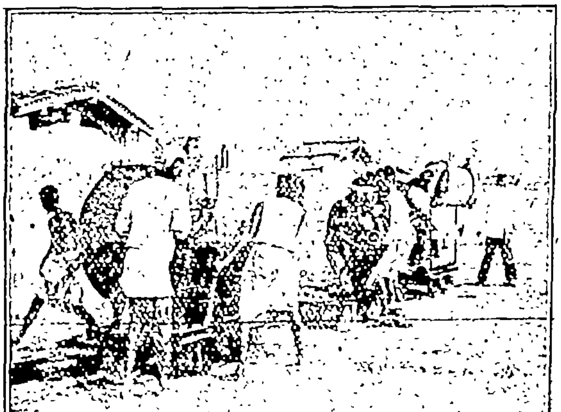
nearest part of the lazaret. The whole distance is about one and a half *kilometres*.

The quality of the well water varies, it is said, greatly. There is apparently communication between the wells and the sea, as when the tides are exceptionally high the well water becomes quite salt. After long drought, when the water level is low, the water is often muddy and brackish, but after rain, and when the level is high, it seems to be of by no means bad quality. When tasted in January last it was quite sweet and pleasant to the palate, but it was impossible to analyse it. This water is used by the employees of the lazaret for washing clothes, for watering gardens, for baths, and similar purposes. Before the distilling apparatus was put up it was the sole supply of the lazaret, but the quantity proved insufficient and the quality too uncertain and variable.

The proper disposal of excreta is one of the most difficult problems that an institution such as a large lazaret presents. Two systems are at present in action at Camaran and neither has given very satisfactory results. They are (*a*) what is known as the Motte system and (*b*) a system of latrine jetties on the sea beach.

(*a*) *The Motte system* is composed of a series of small houses containing the water-closets; drains or "collectors" which convey the excreta to the cesspools; cesspools just outside the cordons; a pump to empty the cesspools; receptacles on wheels into which the excreta are pumped; and, finally, a jetty where the excreta are emptied into the sea. The houses, each of which contains two latrines, are built of brick, covered with plaster, with tile roofs. Most of them are in a bad state, the plaster having more or less completely fallen, and the bricks, thus exposed to the air, tend to crumble to pieces. The latrines ("*à la Turque*") consist of a mere hole in the stone flooring of the hut; such latrines are in use in all Moslem countries. To work well it is essential that the stone should be sloped and grooved so that all liquids and solids are carried to the hole. This precaution was not taken at Camaran, and in some instances the floor actually sloped away from the hole and liquids flowed out under the door. A tap of sea-water exists in each latrine, but it opens horizontally and a strong jet of water spirts against the opposite wall covering the occupant with its splashes. A valve was inserted under each hole, working on a pivot with a counter-weight, but these soon became ankylosed with rust and ceased to work.

FIG. 18.



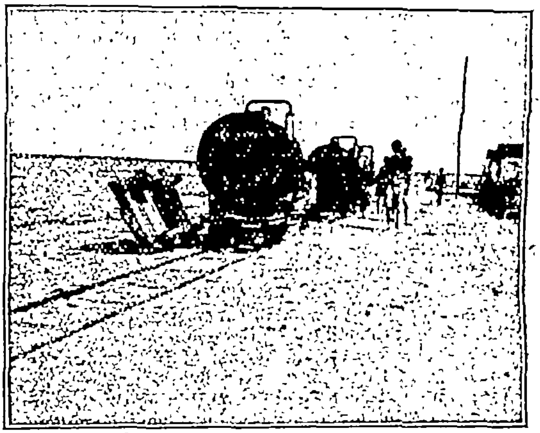
The Motte system at work; bringing the pump and tanks to the cesspool.

The "collectors" are large pipes, *constructed of brick*, covered with cement. Their external diameter is 60 centimetres and their internal diameter 35 centimetres. A pipe of this nature and size is disproportioned to the work it is intended to do; it would require an immense flush to keep it clean, whereas at Camaran the only flush is the small quantity of water used by the pilgrims for their ablutions. It is possible, also, that the internal surface of the collectors was never wholly smooth, being made of brick. As a result many of them became completely blocked and had to be broken open for cleansing. The defects both of latrines and collectors were indeed so serious *that the lazaret authorities* have had to close many of them and the pilgrims have to go to the latrine jetties, to be described later.

The cesspools, of which there are from two to eight at each cordon, appear to have *been well constructed*. They are lined throughout with stone, covered with cement, and are intended to be water-tight. Their covers are either of brick or of armoured cement. Their chief defect is the absence of a ventilating pipe, and as there are no traps on the collectors, and the valves under the latrines do not work, the gases escape from the cesspools into the latrines. The pilgrims complained much of the odours thus caused, which could be smelt not only in the latrines *themselves but also in* the arishes situated at all near the latrines.

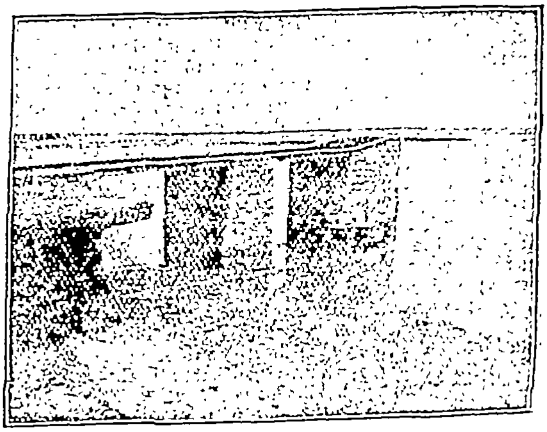
The pump and excreta tanks ("*wagons-tinettes de vidange*") are seen in Figs. 18 and 19. A glance, indeed, at these illustrations gives a better idea than any description of the process of emptying the cesspools and conveying their contents to the sea. Each tank holds a ton of liquid; it requires from 25 to 30 minutes pumping to fill it. The tanks are pushed by Dankali natives along the Décauville railway to a jetty on the shores of a bay to the north *of the last* cordon, where their contents are emptied into the sea. This jetty, known as the "*jetée de vidange*," is seen in Fig. 20.

FIG. 19.



The Motte system at work; wheeling the excreta tanks to the jetty.

FIG. 20.

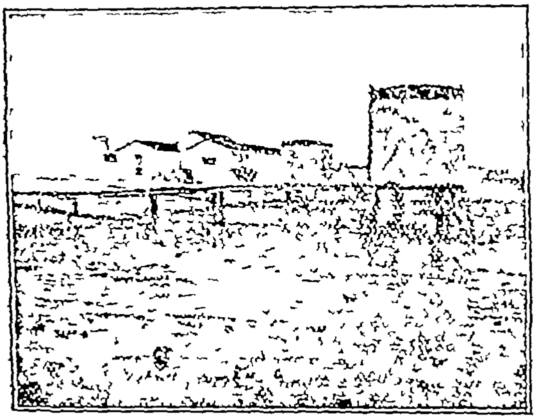


Jetty for disposal of excreta.

The principal disadvantages of the Motte system as adopted at Camaran are the following. The latrines, collectors, and cesspools have the serious defects pointed out above. The process of pumping up the contents of the cesspools involves the use of indiarubber pipes with metal joints. The indiarubber soon deteriorates in a tropical climate; the joints, moreover, are with difficulty kept water-tight (by constantly plastering them over with putty); a vacuum is thus formed only with difficulty; some of the liquid escapes at the joints, and a still larger quantity falls on to the ground when the operation is over and the pipes are unscrewed. The same liquid tends to drip from the tanks themselves during their long transit to the sea. From the first cordon to the jetty is about three miles and this distance has to be traversed many times to empty all the cesspools. The natives dislike the task extremely, and there is no doubt that the work is both very laborious (particularly with a badly laid railway track) and very unpleasant More than once the natives have threatened to strike altogether.

(b) *Latrine jetties* —Owing to the practical failure of the system above described it was soon found necessary to run up temporary jetties on the seashore with latrines at the end, while the whole question of excreta removal could be re-studied and some better and more permanent system found. The character of these jetties, of which there are three in front of each of the first three cordons, is seen in Fig. 21. They are simple wooden structures with matting enclosures at the end. The results they give are very unsatisfactory and unpleasant. The tide goes out a long way beyond their ends, and it is only for a short period before and after high tide that they have water under them The effect can be imagined and need not be described. But it must be added that, as the pilgrims bathe in the sea in the near neighbourhood of these jetties, the condition is one that is likely to be as dangerous as it is certainly unpleasant These jetties should disappear as soon as the new system proposed by the Commission is introduced

FIG 21



A latrine jetty on the seashore.

New system proposed —The Commission recommends the introduction at Camaran of a system of trough closets with automatic flushing tanks. There should be four chalets in each camp of average size, each chalets containing five closets, or 20 in all. It is unnecessary here to describe the details of this kind of closet, so well known to English sanatarians in all parts of the world, but practically unknown in this country. The report of the Commission describes the arrangement in full detail and that of the engineer who accompanied the Commission is illustrated with plans and sections. An arrangement of this kind is probably the most satisfactory one that can be suggested where latrine accommodation has to be found for large numbers of relatively uncivilised persons, as most of the pilgrims are. It requires, it need not be said, to be properly installed in the first instance, and a certain amount of care and attention are necessary to keep it in good working order.

For the ultimate disposal of the excreta it is recommended that a trial should be given to absorbing cesspools—that is to say, to cesspools with unlined bottoms, by which all the liquid portion of the sewage can be absorbed. Such cesspools ("*fosses a fond perdu*") would obviously be undesirable in an ordinary town or village and it is only on account of the exceptional conditions prevailing at Camaran that it becomes possible to approve of their use To begin with, the lazaret is an isolated institution occupied for only about four or five months in the year. During the rest of the year the soil, which would otherwise become permanently fouled, has time to purify itself completely by natural processes of oxidation or nitrification. The soil is, for the most part, an absorbent sand; hard rock occurs here and there, but apparently strata of sand can always be found if the rock be penetrated to a few yards' depth.

In order to ascertain the absorbent power of the soil the Commission caused two such pits to be dug, one near the first cordon and the other near the second. Near the first cordon nothing but sand was met with; near the second (which lies high) alternate layers of rock and sand were found. Measured quantities of fluid—both pure sea-water and sewage from the existing cesspools—were poured into these experimental pits and the time taken for their absorption was noted. The results (the details of which are fully set forth in the Commission's report) were very satisfactory. In some of these experiments eight or ten times the amount of sewage likely to enter any one of the cesspools in 24 hours were poured into the experimental pits at the second cordon (the one offering the least favourable conditions) for days together, without the bottom losing its absorbent power. Apparently (certainly at the pit near the first cordon) the sea-water at high tide infiltrates to the bottom of the pit, and as the tide descends a marked suction action is set up and most or all of the fluid contents are thus absorbed.

The ultimate fate of the solid portion of the sewage is a problem of some interest Cesspits of this kind exist at the lazarets of Suakim and of Tor (at present only for the hospitals and some other portions of these establishments, and it is proposed now to introduce them also for the pilgrims at Tor). Experience there has shown that the solids disappear in a remarkable manner and the pits rarely, if ever, require cleaning out. By the side of some of the pits water-tight cesspools have been constructed in which the sewage deposits most of its solids before flowing into the absorbent pits, but even these "almost never," it is said, require cleaning out. At the village of Camaran also such absorbent pits are in use in most of the better-class Arab houses. I examined several of these and was not a little struck by the complete disappearance of the solids from them. At one house, for example, which had been continuously occupied for five years by an Arab family, the cesspool (only one and a half metres deep) had never required cleaning during the whole of that period. At another, which had been occupied for five and a half years and only evacuated two weeks before it was inspected, I had the cesspool opened up. It was only about a metre deep yet there was not a trace of solid matter in it, and it was entirely odourless. Whether equally satisfactory results will be obtained with the larger pits and the more numerous population represented by the lazaret (when full) only experience can show; and the Commission proposes therefore to try it first at one of the cordons only before introducing it in all. The cesspools will be about two metres in diameter, and from two to three metres deep, according to their position and the nature of the soil. They will be about 20 metres (65 feet) away from the latrines and outside the cordons; their walls will be lined with masonry without mortar for about a metre from the bottom, and with mortar for the rest of their height; they will be covered with a cement vault with a manhole in it They will be ventilated by a pipe carried up well above the roof of the latrines.

There are no surface springs or wells to be contaminated by infiltration from these cesspools. The lazaret is supplied, as already shown, with drinking water distributed in closed pipes, which lie for the most part on the surface of the soil. Care will be taken that these pipes occupy a higher position (i e., further from the sea) than the cesspools, so that even if they should leak there should be no possibility of the contained water being contaminated.

It may confidently be hoped that this new system of latrines and excreta disposal will give better results than does that now in use. All manipulation of the sewage matter will be avoided as it will be disposed of automatically. The wearisome and unpleasant task of pushing sewage-laden tanks for many miles under a tropical sun and on a badly laid railway track will no longer be imposed on the unwilling natives. There will be no pumps or indiarubber tubes to get out of order and leak, and liquid sewage will not, as at present, escape on to the surface of the soil near the cordons or be sprinkled on the railway track from one end of the lazaret to the other.

(To be continued.)

THE BASLE MODEL MUNICIPAL ABATTOIR.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 1339.)

THE slaughter hall for pigs at Basle is as carefully built and organised as is that for the large cattle. The flooring and the walls are made of the same non-absorbent, glazed, and washable materials. But there are different appliances. Thus with pigs the removal of the bristles necessitates a special process. Here, as in most other places, the scalding process is adopted. Within the slaughter hall there are two railed-off compartments or pens which can contain a batch of pigs brought in from the outside to be slaughtered. After these have been killed in the usual way there are revolving cranes ready for use and close at hand. The body of the pig, fastened to the pulley chain, is lifted from the ground; the crane makes a half turn and then lowers the dead animal into a tank containing boiling water. When it has been scalded enough to loosen the bristles the crane raises the body out of the water and deposits it on the long plank tables where the bristles are scraped off. The large open tanks of boiling water naturally give off a great deal of steam, especially in winter, and as this does not readily dissolve in the air or float away a nuisance would be caused unless suitable arrangements were made. Therefore, a large shaft has been fixed near the ceiling with inlets descending closer to the tanks. Hot air is propelled through the shafts and as there are apertures every 30 feet the colder steam and air of the slaughter hall are drawn away into the shaft. On the opposite side of the slaughter hall and along the whole length of the wall there is a row of enamelled sinks about one foot deep. Above each sink there is an ingenious arrangement of taps—one for hot and one for cold water, and a third that provides a mixture of hot and cold water. It is here that the intestines are washed out. The bulk of the foul contents is emptied into metallic receptacles standing on wheels that are placed by each sink and then the gut is washed. Underneath these sinks the floor takes the form of a gutter or open drain, so that anything spilt or splashed or any dirt which accidentally falls on the floor is readily and rapidly washed away. As a result, and though this is very dirty and unpleasant work, there is little or no odour to be noticed.

The water, of which a very large quantity is required, is pumped up from a well dug to a depth of 18 metres, this being two metres, or rather more than six feet, below the level of the bed of the Rhine. Some 70 hectolitres are pumped up per hour. There is a large cold-water reservoir and another in which the water is warmed by steam. To do this pumping and all the other work for which mechanical power is needed there is a steam engine of 125 horse-power. This is used not only for pumping and ventilating and for compressing carbonic acid gas but also to set in motion some American meat-cutting machines. All this is a great convenience to the trade. Pork butchers and others not only avail themselves of the steam power and perfected machinery to make their sausage meat, but instead of taking it all to their shops, where it would soon go bad, they only carry away just enough for their immediate needs and come every day for a fresh supply, leaving the rest in the cold storage where it can be preserved indefinitely. At the same time all this meat is watched, and should any of it go bad or prove not to be good it is at once confiscated. So complete and excellent are all the appliances that skilful men can kill and dress a pig and send it away out of the slaughter hall in 20 minutes. As there is room enough in this hall to kill 80 pigs at the same moment, and though rapidity is not the object held in view, it will be seen that nevertheless the work can be done very promptly and quite quickly enough for all practical purposes. Indeed, it is accomplished with so much greater celerity than would be the case in a private slaughter-house that the time and trouble saved must go a long way towards paying for whatever expense may be caused by the abolition of private slaughter-houses.

A long time ago[1] I described the Berlin cattle station, but that at Basle, though much smaller, is even more perfect in its arrangements. First, I should remark that the site for the abattoir has been well selected from the point of view of isolation and yet of accessibility. On the north-east side there is the Rhine, and the dwellings on the opposite side of the river are more than 200 metres away. To the south-east there is a garden and the remnant of an old rampart and these are inalienable State property. On one side only are there any dwellings, and these are for the most part inhabited by workers at the abattoir. The rest of the surrounding space is occupied by large warehouses. Then the ground, though close to the Rhine, is some ten metres above the river, so there is a good fall for the drainage and no fear is entertained of back currents of sewage or sewer air.

Along the Rhine embankment there is a carriage way with a row of trees, next comes the railway siding, and then there are the slaughter-house grounds. Here, where the cattle vans stop, the whole of the space between the railway metals is built in a concave manner and carefully cemented, and there is a drain under the line. The inlets to this drain are, of course, in the centre and immediately under the middle of the cattle vans or railway carriages. Thus anything falling is drained away and does not sink into the earth. At Basle a landing platform has been carefully built so as to be on just the same level as the floor of the railway cattle vans, and the animals are thus able to step from the van on to the platform with the greatest facility. The platform is, of course, absolutely watertight, being made with paving stones and asphalte between them. At both extremities of the platform there is a fire hose which sends powerful streams of water on to the platform to wash everything away after each arrival of animals. There is an ingenious system of iron bars and railing for the separation of the cattle and other animals. And the vans are strewn with a sandy earth, which is preferable to straw, as the latter when wet becomes very slippery.

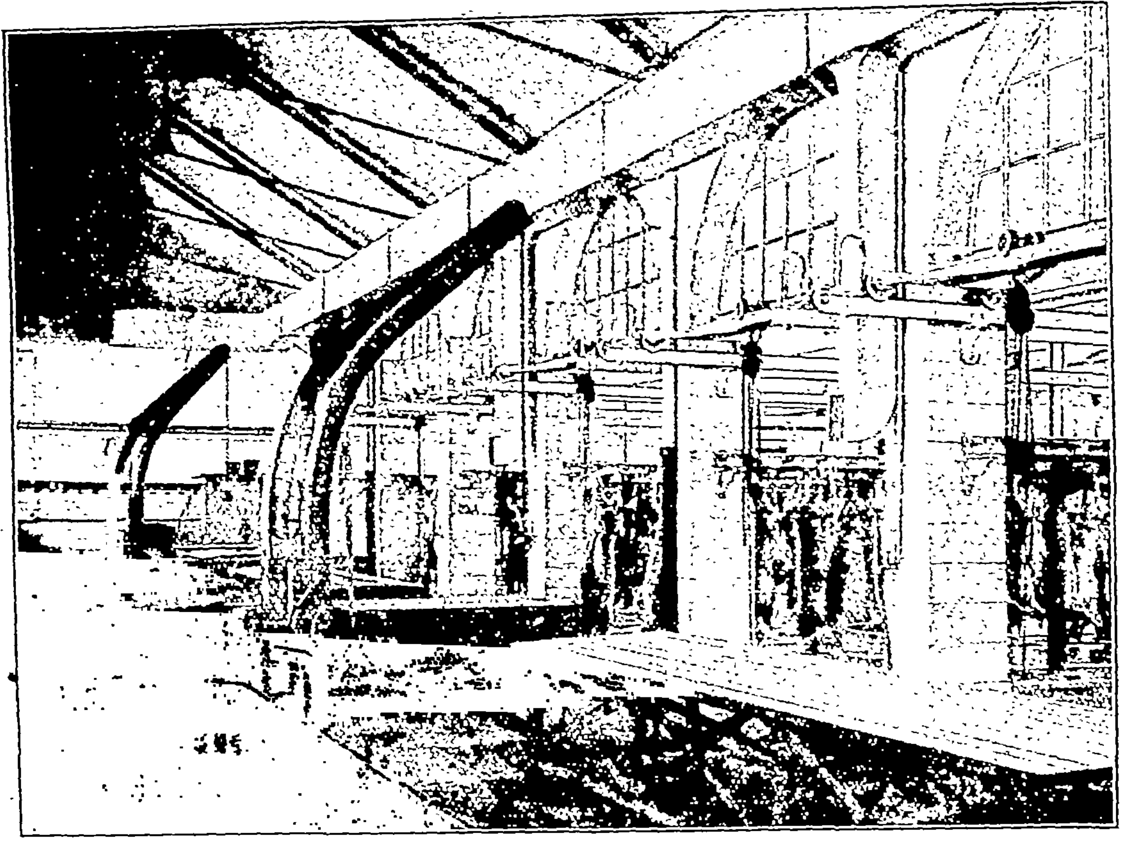
Near the railway siding is a large and model pig pen or stable. In a little outer building there is a cemented and railed-off corner where the pigs are placed on arriving. Here they cannot escape from a strong jet of water which is played upon them till they are thoroughly cleansed. It is only after they have satisfactorily terminated their toilet that they are admitted into the larger building. Within there are numerous partitions. All these railings and gates are, of course, of iron. There are double hinges, so that the doors or gates open both sides, and very ingenious contrivances are used to compel the pigs to go precisely to the partition or pen that has been allotted to them. Granulated porcelain tiles, carefully cemented together, cover the whole flooring. The floor is nowhere absolutely flat but there is a slight slant, so that all liquids drain into a sort of gutter which surrounds all the pens. This gutter is covered with an iron grating. This is found more practicable than a drain-pipe underground. The iron grating can be lifted off, straw or other impediments removed, and the drain itself scoured or brushed and kept thoroughly clean. There is thus no danger of a stoppage in the drains. The pigs are fed from iron troughs which can be filled from the outside by partially lifting a railing in a slanting direction, so that the swill can be poured in without letting the pigs escape. By a crank and windlass arrangement all the windows on one side of the building open simultaneously when a handle is turned. At one end there are boilers in which to cook the pigs' food and serve it hot—at least in winter. Finally, when the pigs are conducted from this ideal abode, where they spend the last days of their existence under the most comfortable and hygienic conditions, there is no need to drive, to push, or to beat them. Passages made by iron railings conduct them to the pen within the slaughter hall. They have no choice as to the road; they must go forward, slowly or quickly; the slightest urging from the attendants suffices to lead them to the final stage of their life's journey.

Near the pigs' pens there are stables for cattle, the quarantine station is at the frontier which is so near and where the cattle on arriving are examined by the veterinary surgeons who detain suspicious cases. This stabling within the abattoir premises is placed opposite the railway siding where the ground becomes narrower. In the broader space there are various large buildings, the largest and central one of which contains the engine and boiler rooms with all the cooling and ventilating machinery, and the cold storage adjoining. On one side of this big block is the model pig slaughter hall and on the other side is the model slaughter hall for cattle. Opposite these fine buildings there remains the old

---

[1] THE LANCET, July 14th, 1894, p. 101.

FIG. 4.

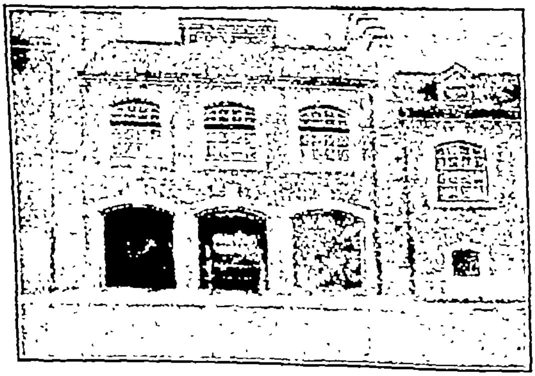


The Basle municipal abattoir. The slaughter hall for pigs. On the left are the iron railings which constitute the pen where the living pigs are brought in. The revolving crane, the circular tanks for scalding, and the tables for scraping off the bristles are close at hand. The metallic ventilating shaft is suspended over the arches, while the inlets for drawing off the steam and air are fixed against every alternate pillar.

slaughter-house, perhaps just so as to show "how not to do it." It consists of long pavilions divided into small compartments where each butcher could work in private. These portions of the buildings are hardly ever used and will doubtless be pulled down to make room for better structures when the need for enlargement makes itself felt. Then there is also a separate building for the killing of sheep and calves about which nothing special can be said, but the disposal of the by-products merits special notice.

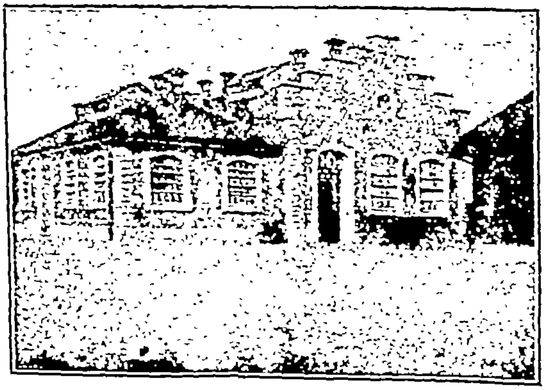
First and foremost there is the important fact that a special structure has been built exclusively for the emptying of the stomachs and larger intestines. The photograph (Fig. 5) which I was able to take illustrates the system. The little structure when approached from the abattoir yard seems to have but one floor with an area and a basement; but if viewed from the outside or from the Rhine embankment it is seen to have two storeys. In the floor above are great stone troughs in which the contents of the larger intestines and stomachs are emptied and this material falls into tank carts that stand ready underneath. When one of these

FIG. 5.



The Basle municipal abattoir. Exit outside the abattoir grounds from the special building or emptying the stomachs and larger intestines. The tank carts receive the visceral contents from above.

FIG. 6.



The Basle municipal abattoir. The tripe-preparing department. Calves' heads, sheep's feet, &c., are boiled in the smaller building to the left. The open louvre windows, the lantern ventilators, and patent cowls on the roof are supplemented inside by air shafts and motor fans.

tanks is full it is closed, the horses are brought out of the neighbouring stables harnessed, and the tank is taken away. It will be noticed that these tank-carts are outside the slaughter-house premises, though they are filled from within. They therefore do not enter that part of the abattoir where the meat is conveyed out of the slaughter-house, where these carts never go. Then it will be observed that where this dirty work is done nearly all the wall space is perforated by windows or doors and the windows have louvre openings to direct the draught upwards. But not content with the ventilation and the through draughts thus provided and for fear that the windows might at any time be shut there is a large lantern ventilator on the roof which cannot be shut. Then the troughs themselves also act as ventilators, for they have openings about a foot square, through which the refuse falls into the cart below, but air also passes through.

The tripery is next to this compartment and a small opening in the wall enables the men to throw the tripe through. As it falls in the tripery it is placed in deep troughs made of granite where it is left to soak. The floors throughout are of granite flagstones carefully cemented together and the walls, to a height of five feet, are of glazed bricks. Thus all dirt is readily washed away and none can be absorbed. But the elaborate methods of ventilation are still more remarkable. The accompanying illustration (Fig. 6) shows two buildings side by side. In the larger structure the tripe is dressed; in the smaller the heads and feet are boiled. It will be noticed that throughout louvre windows abound on all the external walls. But there are also two large glass-framed lantern ventilators on the apex of each roof and a considerable number of Dr. Platner's ventilating cowls. It might be thought that such abundant means of natural ventilation would suffice. All scientific authorities, however, know full well that natural ventilation is *not* to be relied upon. Consequently there are air shafts along the inner walls and near the ceiling. An electric motor causes a fan to revolve so as to propel through these shafts some very hot air. This is easily obtained as throughout the building there are pipes supplying hot and cold water for the preparing of the tripe and boiling of the feet, the calves' heads, &c. The air shafts have small openings every three feet to draw away the steam and vitiated air.

On the other side of the building, constructed especially for the emptying of the contents of the stomachs and large intestines, is a small but wonderfully airy building reserved exclusively for the making of sausage skins. In this work it is impossible to prevent a very unpleasant odour, therefore it should be carried out in a separate and specially well-ventilated building. Consequently this department is kept scrupulously clean. The walls and the floor are of water-tight non-absorbent material. Thus they can be, and are, constantly washed with a deluge of water and therefore the odour does not adhere to them, particularly as the abundance of light and air further helps to dispel the sickly smell of the dried gut.

Such are some of the most striking features of this recently built and model abattoir. But it will be said that though all this is admirable the cost is likely to prove prohibitive. Such, fortunately, is not the case. The butchers have to pay to the municipality 7 francs (*5s. 7d.*) to kill a bull or bullock, 4*s.* for a cow or heifer, 1*s.* 3*d.* for a calf, 8*d.* for a sheep, and 2*s.* for a pig. The last charge includes the cooking of the head and feet. Then there is another source of revenue—namely, £10 a year for a large cage and £6 a year for a cellar to keep sausage meat and other meat. Then, again, when there is a case of tæniasis and cysticercus, a larval form of tapeworm, the carcass need not be destroyed. It must be placed in the cold storage under lock and key and the key is kept by the director of the abattoir for three weeks. This procedure kills the larvæ and the meat can then be safely consumed. But for the cold storage it would have to be destroyed, so that the butcher is pleased to pay the necessary rent and thus to escape a consider- able loss. Nevertheless the cold-storage department does not pay and for the simple reason that it is just double the size that is at present required. If all the space available was utilised it would pay. It was, however, thought best to make provision for the probable increase of the population. Actually the receipts cover the working ex- penses but there is nothing remaining over to create a sinking fund. With regard to the slaughter-house the financial position is satisfactory, for the receipts suffice to pay 4½ per cent. interest on the loan capital and 2 per cent. to the sinking or amortisation fund.

Therefore it will be seen that it is possible to build perfectly satisfactory public slaughter-houses without involving the taxpayer in unremunerative enterprises. On the contrary a valuable public property is created; at the same time a great guarantee is provided in regard to the wholesomeness of the food-supply and thus the outlay is rendered doubly remunerative.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Ingleby Lectures.

IN his second lecture Dr. Thomas Wilson proceeded to consider the diagnosis and treatment of inflammatory conditions of the uterine appendages, basing his remarks, as in the previous lecture, on a series of 260 cases which had been under his direct supervision. The origin of the inflammatory condition in this series of cases was directly connected with the puerperal state in considerably more than half the patients (160), and in a general manner as regards the period of infection the cases were divisible into an early and a late group, the infection occurring in the latter group after the lapse of two or three weeks. Dr. Wilson emphasised the necessity for diagnostic purposes not only of a thorough local examination but also of a careful consideration of all the bodily functions, and he mentioned the main symptoms and physical signs on which reliance could be placed. In association with the cases of serous inflammation he noted a distinct tendency to localisation of the effused fluid, and in this condition he thought that the patient's aspect was devoid of the anxious, drawn, and toxic look so frequently seen in septic cases, whilst the swelling itself was, as a rule, elastic. He deprecated too great reliance upon leucocytosis as being diagnostic of pus formation, well-marked leucocytosis occurring in purely serous cases. With regard to the treatment of serous collections he advocated incision and drainage, rapid improvement being thereby attained, and he recommended the opening and draining of all collections of pus but emphatically deprecated more radical treatment. Dr. Wilson discussed gonorrhœal inflammations at some length and advocated in chronic and subacute cases the use of hot douches, glycerine tampons, and electric heat baths. In the concluding part of his lecture he expressed the hope that newer methods of treatment would be initiated with the object of stopping disease at the outset and that then, as a consequence, the more or less barbarous methods now adopted would become matters of history.

The Birmingham Medical Benevolent Society.

The object of this society is to aid medical men and their families who have fallen into necessitous circumstances. It is at present providing 23 annuities and it has invested funds to the amount of £15,940. The area of its operations extends for 100 miles round Birmingham and, as Sir James Sawyer points out, there are in the area about 4000 medical men, of whom less than 400 are members of the society. This is much to be regretted, for the design of the society, mutual help, should appeal strongly to a class of men many of whom are liable to be cast out of active work at any moment by many causes. At the recent annual meeting Dr. E. Rickards resigned his position as president at the end of his term of office and Dr. E. B. Whitcombe was appointed in his place. Mr. W. F. Haslam and Mr. F. Marsh were appointed treasurers in the place of Sir Thomas F. Chavasse, Mr. Haslam having first resigned the secretaryship which he had held for a period of 16 years. Dr. J. E. H. Sawyer was appointed secretary, and Sir Thomas Chavasse, Dr. E. Malins, and Mr. A. C. Underwood were elected to three vacant positions on the court of directors.

The Birmingham Lying-in Charity.

The governors of the charity are establishing a new maternity and training hospital with the object of meeting a long-felt want in this city in which, as the chairman and treasurer state in their appeal, there has hitherto been "no institution for the reception of serious maternity cases except in connexion with the Poor-law." The total sum needed for land and buildings is £15,500 and for additional income £800 a year. Towards the former £13,400 have already been collected and the chairman and treasurer now appeal for more, especially to the women of Birmingham, to provide the £2100 for buildings and the necessary annual income. It is to be hoped that the appeal will receive the answer which it deserves and in that case more than the necessary sum will be forthcoming, for the suffering which it is sought to alleviate has the sympathy of all peoples and all classes.

The Employment of Specialists in Workhouse Infirmaries.

It is quite obvious that the medical officer of a workhouse cannot be expected to be capable of dealing in the most satisfactory manner with all cases which require operative interference, yet until quite recently it has apparently been the custom at Aston, as at many other places, that the medical officer should do all that has to be done or himself pay a specialist to do any operations which he does not feel himself competent to undertake. It seems, however, that at Aston this custom has gone on rather from want of knowledge than from design and when the matter was brought to the notice of the guardians at a recent meeting they took the proper step and authorised the employment of a specialist in all cases in which the medical officer desired help. Their action can be cordially recommended to all boards of guardians who have not yet taken proper action in this matter.

Suggested Compulsory Notification of Consumption.

At a recent meeting of the Yardley district council it was proposed that the council should express its conviction that pulmonary tuberculosis should be included amongst the compulsorily notifiable diseases. The medical officer of health was not prepared to support the motion; nevertheless it was carried by a vote of 16 to 1, and it was decided that a copy of the resolution should be sent to the Local Government Board. There is but little probability that the wish of the Yardley council will be gratified for some time to come but the action which it has taken may be welcomed as a sign that the infective character of the disease is becoming better understood, for as the knowledge of the danger spreads the task of medical men who have to deal with the sufferers and their friends will be considerably lightened, whilst more care will be taken to deal effectively with the sputum, with the result that much trouble and many lives will be saved.

Food for School Children.

The education committee has had the matter of providing meals for children under its consideration for some time and it appears from the evidence which it has gathered that something must be done. The voluntary agencies have ceased work and the number of meals provided by the guardians has fallen considerably below that which is well known to be necessary. There are 98,000 children on the registers of the public elementary schools and it is estimated that at least 4500 of them need food before the opening of the schools each morning. It is proposed to spend £2000 per year out of the rates for the purpose of providing breakfasts for these children and to this there can be no objection, for the children must not be allowed to suffer; but it is to be hoped that the authorities will not permit parents who have the necessary means to shirk their personal obligations.

Bequests to Wolverhampton Hospitals.

By the will of the late Miss Perry of Wergs Hall, near Wolverhampton, a large sum of money is bequeathed to the hospitals of Wolverhampton. The Wolverhampton General Hospital, the Women's Hospital, and the Queen Victoria Nursing Institution will each receive £5000, the Eye Infirmary £3000, and the Blind Institute £2000.

May 28th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Port Sanitary Authority and the Dangers of Anthrax; Medical Inspection of Emigrants.

IN the annual report of the medical officer of health to the port sanitary authority the statement appears that the constant recurrence of cases of anthrax amongst labourers and others working cargoes on ships or carting material into the city gave rise to some anxiety, and the matter was investigated by the assistant port medical officer. It was ascertained that during the three years ending December, 1906, no less than 21 cases, mostly of dock labourers, had come to the knowledge of the department; all of them, with one exception, were cases of the external form of anthrax—namely, malignant pustule. 14 of the cases ended fatally. Much has been done by the officials of the Home Office and the Liverpool port sanitary authority to spread a rudimentary knowledge of the first symptoms of the disease among dock labourers and others; they also recommend the wearing of gloves, persal cleanliness, and early attention to treatment, and advise labourers with cuts or scratches on the hands, face, or neck to avoid handling those products which cannot be disinfected without serious danger to the material. Dr. E. W. Hope states that anthrax ought to be placed in Liverpool amongst the compulsorily notifiable diseases under the Infectious Disease (Notification) Act, 1889. During the year 1906 there were seven cases reported amongst dock labourers handling dry hides and skins from various parts of the world. The medical inspection of emigrants on board the outward-bound steamers is carried on by Mr. J. de Vere Hill and Dr. J. R. Stocker, the medical officers appointed by the Board of Trade. Emigrants showing symptoms of illness, or coming from localities where infection is rife, are liable to be rejected. One of the port sanitary inspectors is present at these Board of Trade clearances. There were 407 inspections during the year 1906 and 111 persons (mostly children) were rejected on account of disease of an infectious nature, or because of being under suspicion of developing such. These persons were taken charge of by the inspector who made arrangements for their removal, if necessary, to hospital. The constant stream of emigration westward to Canada and the United States of America from all parts of the continent of Europe and the British Isles finds in the port of Liverpool its main and natural outlet. This increased passenger traffic brings with it increased risks of imported disease.

Home for Epileptic Children at Maghull.

In view of the great need for further provision for the care and treatment of epileptic children the committee of the Home for Epileptics at Maghull has decided to erect a special building for boys and girls, the estimated cost of which, with furniture, will be £8000. So far £3255 have been promised, Miss Chilton (lady superintendent of the home), heading the list with a contribution of £800.

Hospital Saturday Collection.

The thirty-seventh annual collection on behalf of the medical charities of Liverpool was made in the workshops, offices, and warehouses of the city on Saturday, May 18th. Last year's total was £9142 and special efforts were made on this occasion to raise £10,000. The movement initiated last year by Mr. W. P. Hartley and Alderman L. S. Cohen whereby ten ladies and gentlemen each promised to add 10 per cent. to any increase which might take place in the Saturday and Sunday funds will continue to apply to this year's receipts, and inasmuch as the Hospital Sunday collection shows a substantial increase over that of 1906 it is hoped that the medical charities will be materially benefited as a result of the generous offer. The ladies' street collection will take place on Saturday, June 8th.

(FROM OUR OWN CORRESPONDENTS.)

Institution of Founders' Day at Queen Margaret College, Glasgow.

AT the institution of Founders' Day, which was held on May 23rd, a large number of students, past and present, assembled at Queen Margaret College, which is the section of the University of Glasgow devoted to the education of women. Miss Galloway, LL.D., gave an interesting account of the rise and progress of the higher education of women movement in Glasgow. In the course of her remarks she spoke of the splendid work done by the late Mrs. Campbell, LL.D., of Tullichewan. Mrs. Campbell was the last of the founders and it was felt that something should be done to perpetuate the memory of the great services rendered to Queen Margaret College by Mrs. Campbell, Mrs. Elder, the donor of the College buildings, and Professor John Young, the founder of the medical school. Miss Galloway accordingly proposed a motion to the effect that an annual meeting of present and past students of Queen Margaret

College and Gilmorehill should be held in May. She further proposed that this meeting should be called Founders' Day. Besides commemorating those who had gone before Founders' Day would do much to keep together past students and to unite all more closely together. Miss Galloway stated that so long as she remained at Queen Margaret's she would give the annual "At Home" and she expressed the hope that Founders' Day would thereafter be kept up by the Students' Union and Graduates' Association. The motion was adopted and it was resolved to make Founders' Day an annual event.

"Fresh Air Fortnight" Scheme in Scotland.

To those interested in the physical well-being of the young children in our large cities the report recently published by the Fresh Air Fund Committee should cause considerable gratification. In a list published of the towns now covered by the Fresh Air Fund Aberdeen is represented by 3000 children, Dundee by 3000 children, Edinburgh by 4000 children, and Glasgow by 6000 children. A noteworthy feature of the report is that there are no expenses of management in connexion with the fund. Every penny subscribed goes to the children in food or fares.

Sewage Purification Works in Scotland.

It is interesting to note in connexion with the sewage purification scheme for Dumbarton that 18 Scotch burghs have bacteriological systems of sewage purification already in operation. In seven cases systems are being laid down and in the case of 14 burghs schemes are under consideration.

Cerebro-spinal Meningitis.

Another death from this disease took place in Dundee during the past week. The victim was a young man aged 25 years. This is the first adult who has succumbed from the disease in Dundee. Two suspected cases of cerebro-spinal fever have been removed to the Forfar county isolation hospital.

Aberdeen University Anatomical and Anthropological Society.

At a meeting of this society held at Marischal College last week Professor R. W. Reid conducted the members round the new anthropometrical museum and gave an excellent description of the various sections, describing more minutely certain articles which were especially interesting for their local associations or extreme rarity. Afterwards Dr. Moir demonstrated a number of specimens from West Africa.

Aberdeen and Small-pox.

Since March, 1904, no cases of small-pox have occurred in Aberdeen till the past month, when the steam trawler *Machoda* arrived from Lisbon with a crew, mainly Portuguese, one of whom was suffering from the disease. The patient, who was removed to the city hospital, suffered from a comparatively mild attack of small-pox and has made an excellent recovery. No further cases have arisen among the crew or among persons in contact with them.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Post-graduate Classes in Dublin.

THE syllabus of lectures and demonstrations in connexion with the School of Physic of Trinity College has appeared and differs little from former editions. This course has during the last three years proved very comprehensive, effective, and popular. It has been largely attended by medical men from the country. It will begin on June 17th and will terminate in three weeks—an arrangement which suits the practitioner from the country who cannot leave his duties for any long period. The medical school of the Catholic University in connexion with the Mater Misericordiæ Hospital, which is the largest hospital in Ireland giving clinical teaching, advertises a post-graduate course to commence on June 10th and another—an autumn course—on Sept. 16th. Each course will extend over a period of three weeks. The registrar of the medical school, Cecilia-street, Dublin, will furnish any particulars of these courses. The Royal College of Surgeons in Ireland will arrange also for two courses of lectures and demonstrations, the first to begin on June 10th and the second on Sept. 23rd. In addition to the usual subjects of instruction practical demonstration of operations on the cadaver will be included. Each course will occupy three weeks. The inclusive fee for each of the above-mentioned courses is 5 guineas.

Royal Medical Benevolent Fund Society of Ireland.

The central committee of this society passed the following resolution at their last meeting:—

> The central committee of the Royal Medical Benevolent Fund Society of Ireland desire to express to Dr. Richard Purdon of Belfast their high appreciation of the valuable services he has rendered to the society in the capacity of honorary secretary of the Belfast branch for ten years, and have learned with regret of his resignation of this position.

Health of Belfast.

At a meeting of the public health committee held on May 23rd it was reported that 24 cases of cerebro-spinal fever had been notified during the week as compared with 29 in the previous week. It is said that the type of the disease is not so severe now as in the early cases. The total number of cases notified in Belfast up to May 23rd is 445, with 316 deaths. Three deaths have occurred in Lurgan workhouse from the disease, the last being on May 23rd. There is at present an epidemic of measles in the north portion of the city and it has been found necessary to close one of the schools. It was also reported that proposals would be submitted next week by which the Forster Green Hospital would supply 25 beds for consumptives. The subcommittee appointed for the purpose recommends fortnightly cleansing of ashpits but has not yet decided on the adoption of ashbins, and all the rent agents in the city have been summoned to meet the committee to discuss the question.

Health Prosecutions in Belfast.

The Belfast city corporation has been showing considerable activity in prosecuting offenders for violation of the Public Health Acts in connexion with milk (exposing it for sale in unwashed vessels and allowing rubbish to be conveyed in milk-carts), for keeping pigs within 15 feet of a dwelling-house, and for not taking down houses in a dangerous condition. This action of the city council, though belated, is to be commended; it is entirely due to the revelations brought out at the Health Commission, which have compelled, through the force of public opinion, the city council to put in force its Acts. In the past the excuse was too often put forward that it had not power. Its action now supports the view of the Local Government Board that it had ample power under its sanitary Acts if it would only put them in force.

Asylum Accommodation in Belfast.

It is clear from a report presented to the finance committee of the Belfast city council on May 27th that the time has arrived when it will be necessary to erect further villas and administrative buildings at Purdysburn city asylum where at present there is accommodation for 400 patients. At the Grosvenor-road institution (the original asylum) there are still 680 inmates and at the Ballymena annexe 62, and to provide room for these additional 750 patients would cost about £75,000, and to build administrative buildings (hospital, churches, recreation hall, workshops, farm buildings, &c.) a sum of £35,000 would be required—that is, £110,000 in all. This most important question was postponed for further discussion.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Syphilitic Nephritis.

AT a meeting of the Hospital Medical Society held on May 18th M. Dufour and M. André Martin communicated the case of a patient suffering from syphilitic nephritis with copious albuminuria. This condition lasted for two and a half years, after which the patient recovered. The two observers stated that they had noticed that a salt-free diet exercised a most favourable influence upon the patient who rapidly relapsed whenever a little salt was added to his diet on some four or five occasions. The effects of mercury in syphilitic nephritis are very variable. Sometimes the œdema disappears and the quantity of urine lessens under its use, while at other times the drug has apparently no effect.

The Action of the Thyroid Gland upon the Hairy System.

At a recent meeting of the Society of Biology M. Levi spoke of the action of the thyroid gland upon the hairy system. Pathology affords numerous examples of this as in myxœdema, whether spontaneous or acquired by operation, in both of which conditions the hair falls out, or in cases of hypothyroidia when premature greyness occurs. He mentioned the case of a stunted (*arriéré*) child suffering from hypothyroidia whose hair was quite white. Thyroid insufficiency again shows itself in the falling of hair during pregnancy, during general infections, and during the second period of syphilis. In this last condition falling of the hairs at the extremities of the eyebrows is a common symptom.

The Provision of Employment for Widows and Orphans of Medical Men.

The General Association of French Medical Men recognises that any effective scheme of helping medical men's widows and orphans who, though capable of work, have been left destitute must include the provision of employment and situations of which they are capable rather than the giving to them continual monetary aid which is too often insufficient and ineffective. At the general meeting on April 14th it was decided to organise an agency for providing both work and situations in accordance with the recommendations contained in a report presented by Dr. Bouloumié. The wish has further been expressed that the scope of this organisation, with the same provisions as have been made for the central society, may be extended to the whole of France with the consent of the united societies so that the association's beneficiaries may everywhere profit by it. The end particularly aimed at is the *provision of permanent situations*, but the search for employment suitable to each individual case is often a lengthy proceeding, and the association, by offering immediate work, will provide means for waiting and will help in the search. To carry out these plans the central society has appointed a special relief committee which is to delegate to a ladies' committee those parts of its duties which personally concern its clients. It has opened in its secretarial offices a register of "situations vacant and wanted," reserved for cases of distress amongst families of medical men and it has obtained the support, on the one hand, of the medical press syndicate to give these lists all necessary publicity, and, on the other hand, of various charitable employment organisations, so that work in accordance with the requirements of each individual case may be obtained at once. The institution of this new scheme of relief cannot fail to command the sympathies of the entire medical profession who know well with what difficulties the task of efficiently relieving the wants of a destitute person for life is beset, and what a large number of families of medical men live after the breadwinner's death in need and in daily dread of destitution.

Obituary.

Death continues to be busy among the members of the medical profession in France. The latest to pass away is Dr. Charrin. He recently died at the age of 52 years. He was professor at the College de France, an *agrégé* of the Paris Faculty of Medicine, and physician to the hospitals. A pupil of Pasteur and of Professor Bouchard, he has left numerous works dealing with embryogeny and bacteriology which have gained him great reputation throughout the scientific world. He had been for many years physician to M. Loubet, late President of the Republic.

The Thyroid Treatment of Infantilism.

At a meeting of the Hospitals Medical Society held on May 24th M. Apert mentioned the case of a patient the subject of hereditary syphilis. He had always been a sickly child and at the age of 12 years his growth stopped completely. Moreover, his weight began to decline. When he was 14 years of age thyroid treatment was begun, with the result that the child, who for two years had remained absolutely stationary, rapidly made up for lost time. He is now 16 years of age, appears quite normal, and was recently accepted for military service.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Forty Families Poisoned by "Preserved" Tunny.

THE Tuscan press, professional and lay, has been much exercised by the wholesale poisoning (fortunately without fatal consequences) of some 40 families at Figline Valdarno after the consumption of "preserved" tunny. Grave gastric and intestinal trouble was the symptom in each case and the local sanitary authority had no difficulty in tracing it to the ingestion of that favourite edible among the Italian *bourgeoisie*—tunny fish reduced to paste and preserved in tins. The examination by the said authority was confirmed by three experts commissioned from headquarters, who found that the fish had been "badly prepared," and that the consignment consumed at Figline Valdarno especially was charged with *microbes other than "benevolent."* Every shop where the article was on sale had forthwith to give it up to the authorities, while the Spanish firm from which it had been imported was promptly advised of the *quality* of its wares. As I have said, "preserved" tunny is in much favour as food with the Italian lower middle class and is often to be had at pretentious restaurants, where, eaten in conjunction with "fagiolini" (*haricots verts*), it forms a piquant, even pleasant addition to the *menu*. Indeed, the English-speaking visitor is often tempted by the attractive look of the dish to make a trial of it and, finding it in Italian phrase "molto saporito," to make it the chief part of a noonday or evening repast. The "fagiolini" accompanying it, moreover, are oftener than not "preserved" in tins and deleterious in consequence, so that if eaten with bread which owes its seductive whiteness to alum, and washed down with "Chianti," the "prickly after-taste" of which, so pleasant at the time, is due to the same astringent, the adventurous and unsuspecting consumer is likely to find by subsequent experience that his meal has been somewhat of a chastened joy. However, *forewarned, forearmed*; and the systematic "boicottaggio" (boycotting) of tinned-foods on the part of the travelling public is beginning to reduce the consumption and the sale of such edibles (especially when the date of the tinning process is withheld) and to minimise the occurrence of such "avvelenamenti" (poisonings) as that reported officially from Figline Valdarno.

A "Civic Hospital" at Caprera.

The first centenary of the birth of Giuseppe Garibaldi will, on July 7th next, be celebrated all the world over wherever two or three Italians can *meet in the* name of "Italia Unita ed Indipendente." A special feature of the programme, now in course of completion for Italy, will be a pilgrimage to the island of Caprera, the sea-girt rock in the Straits of Bonifacio which the hero purchased out of his South American savings, to which he retired when "at bay," after the failure of this or that raid upon the temporal power and on which he died just a quarter of a century ago. That pilgrimage will consist of many thousands of visitors to his tomb, mainly of Italian, but also, to some extent, of English-speaking nationality. To commemorate this tribute to the "Manes" of the most unselfish of "liberators," his son and daughter-in-law (General Ricciotti and Madame Garibaldi) propose the dedication of a column suitably inscribed, and, more significant still, the erection of a "*Spedale Civico*" for the rehabilitation (presumably) of the convalescent among the "*classi meno agiate*" (less favoured classes). Nothing would have gratified the humane and tender-hearted hero more than such a hospital, devoted as he was in his declining period to public sanitation in its widest sense and to the physical well-being of the compatriots whom he had helped to *disenthrall*. His scheme for the reclamation of the Campagna and its restoration to the salubrity which it enjoyed under the Antonines was but one of the many proofs which he gave of this humanitarian spirit—a spirit which went out lovingly even to the lower animals, notably to the birds that are so ruthlessly shot down all over Italy. In his dying hours he found it (according to Madame Garibaldi) a pleasing distraction to watch from his pillow his little feathered favourites as they fluttered down on his window-sill, as if prescient of the departure of their protector. Henceforth, it seems, no wild birds will be killed in Caprera—a law in keeping with the all too tardy legislation by which the wholesale destruction of the feathered tribe is being arrested throughout Italy—not only to the restored amenity of the woodland but to the safeguarding of the root-crops so disastrously affected by the worm.

"Propaganda Sanitaria."

Such is the title of a new periodical to be published at Florence under the eminently capable direction of Professor Di Vestea, Professor Lustig, and Professor Sclavo, its *rédacteur-en-chef* being Professor Mercanti. Its object is to popularise the laws of health and to bring the "norme

College and Gilmorehill should be held in May. She further proposed that this meeting should be called Founders' Day. Besides commemorating those who had gone before Founders' Day would do much to keep together past students and to unite all more closely together. Miss Galloway stated that so long as she remained at Queen Margaret's she would give the annual "At Home" and she expressed the hope that Founders' Day would thereafter be kept up by the Students' Union and Graduates' Association. A special feature of the programme, now in course of completion for Italy, will be a pilgrimage to the island of Caprera, the sea-girt rock in the Straits of Bonifacio which the hero purchased out of his South American savings, to which he retired when "at bay," after the failure of this or that raid upon the temporal power and on which he died just a quarter of a century ago. That pilgrimage will consist of many thousands of visitors to his tomb, mainly of Italian, but also, to some extent, of English-speaking nationality. To commemorate this tribute to the "Manes" of the most unselfish of "liberators," his son and daughter-in-law (General Ricciotti and Madame Garibaldi) propose the dedication of a column suitably inscribed, and, more significant still, the erection of a "*Spedale Civico*" for the rehabilitation (presumably) of the convalescent among the "*classi meno agiate*" (less favoured classes). Nothing would have gratified the humane and tender-hearted hero more than such a hospital, devoted as he was in his declining period to public sanitation in its widest sense and to the physical well-being of the compatriots whom he had helped to disenthrall. His scheme for the reclamation of the Campagna and its restoration to the salubrity which it enjoyed under the Antonines was but one of the many proofs which he gave of this humanitarian spirit—a spirit which went out lovingly even to the lower animals, notably to the birds that are so ruthlessly shot down all over Italy. In his dying hours he found it (according to Madame Garibaldi) a pleasing distraction to watch from his pillow his little feathered favourites as they fluttered down on his window-sill, as if prescient of the departure of their protector. Henceforth, it seems, no wild birds will be killed in Caprera—a law in keeping with the all too tardy legislation by which the wholesale destruction of the feathered tribe is being arrested throughout Italy—not only to the restored amenity of the woodland but to the safeguarding of the root-crops so disastrously affected by the worm.

"Propaganda Sanitaria."

Such is the title of a new periodical to be published at Florence under the eminently capable direction of Professor Di Vestea, Professor Lustig, and Professor Sclavo, its *rédacteur-en-chef* being Professor Mercanti. Its object is to popularise the laws of health and to bring the "norme d'igiene" within the purview of all Italians, high and low, so as to make the inhabitants of every town and the inmates of every dwelling intelligent coöperators in the carrying out of the great "Codice Sanitario" devised and reduced to practical working by the Garibaldian Surgeon-General Agostino Bertani of Genoa. The new venture "deserves," and I hope, will "command" success.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Cerebro spinal Meningitis.

THE local newspapers announce that the Chief Sanitary Municipal Council of Constantinople has found that several isolated cases of cerebro-spinal meningitis have occurred in different districts of the metropolis. Thus from the mortality returns for last week it is seen that out of the total of 288 deaths one died from scarlet fever, three from small-pox, three from enteric fever, 45 from tuberculous diseases, and four from cerebro-spinal meningitis. Precautions have been taken to prevent the spread of the disease.

Enteric Fever at Philippopolis.

From Philippopolis comes the news that an epidemic of enteric fever has broken out in that city. The epidemic seems to be of an alarming character, as it is reported that over 1000 people have been attacked in the course of a few days.

Pilgrimage Statistics.

The total of this year's pilgrims to Mecca and Medina was 281,100. Of this number 113,000 were Ottoman subjects, 12,000 were Bokhariotes, 4500 were Malays, 40,000 were Indians, 10,000 were Afghans, 16,000 were Russians, 15,000 were Persians, 13,000 were Soudanese, and 17,000 were Moroccans. The state of health of the pilgrims on the way to and from the holy cities of Islam has been very satisfactory, which is partly due to the more speedy transport and communications by means of the new Hedjaz railway.

Two Cases of Remarkable Longevity.

In the village of Biréli, near Anamore (vilayet Adana), there died last week a Mussulman, Khalil Codjaoglou by name, at the age of 115 years, the cause of death being a mere accident. He enjoyed good health to the very last. His youngest son was only 20 years old. Another case of longevity has occurred at Smyrna. This time it was a Greek named Frankaki who died when he was 108 years old. He is said to have had all his teeth, was never ill, and was to the last moment in full possession of his mental and physical faculties.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Legal Position of Unqualified Medical Practitioners and Quack Medicines.

SOME of the abuses which are connected with quackery have been recently engaging the attention of the higher courts of justice, and in a judgment delivered not long ago the Supreme Court decided that for the conviction of a person charged with an offence of this description it was not necessary to prove that the treatment employed by him was detrimental to the patient; the mere fact that a person offered medical advice or undertook the medical treatment of a patient without being in possession of proper qualifications was sufficient to bring him under the power of the law. If he be convicted as a quack it must be proved that he received payment on more than one occasion for his medical work. The punishment was then much more severe. Several ordinances of the Ministry of the Interior have quite recently been published dealing with the sale of proprietary and other medicines of secret composition and announcing that the advertisement of remedies which are sold by pharmaceutical chemists and in the so-called Apotheke is allowed only under the restriction that such advertisements do not contain medical advice and recommendations from other than medical men, and that the statements made are not preposterous or misleading. Medicines, the composition of which has either not been disclosed to the Board of Health or has been intentionally misdescribed, must not be sold in these shops, even on the request of a qualified medical man. Another ordinance deals specially with electrical apparatus and so-called "cures." Quite a number of appliances are advertised in the Austrian newspapers under various high-sounding names, such as the "electro-vitalizer" and others of a like kind. The majority come from America but some come from England and some come from Germany. Nervous disorders and diseases of the ear are the class of cases mainly appealed to in the advertisements of the "cures." Acting on a suggestion made by the Austrian Antiquackery Society, the Minister of the Interior has forbidden the newspapers to accept these advertisements and has issued a warning to the public informing them of the fraudulent nature of such statements.

Puerperal Fever and its Treatment.

Dr. Latzko read recently before the Gesellschaft der Aerzte a paper on the Treatment of Puerperal Fever and put forward some new views relative to surgical operations on the abdomen and genital organs. He recommended active measures in regard to the peritonitis so often seen post partum and in regard to the parametritic process which he believed to be of the same nature as the periphlebitis of the uterine veins. The parametritis was therefore aptly called by him "phlegmasia alba dolens ligamenti lati." For this condition he operated by the vaginal route and if possible he extirpated the uterus, thus removing the cause of septic infection of the organism. He preferred supravaginal amputation to any other procedure in such cases. If diffuse peritonitis was present he opened the abdomen by means of a large incision and drained it, leaving it open for a few days until the condition of the secretion improved. In serious pyæmic affections of the pelvis, such as metrophlebitis, he opened the veins after double ligature and drained the vessel after removing the thrombosed masses in a way similar to that employed by otologists when dealing with thrombosis of the sinus of the internal jugular vein. In less urgent cases a trial of collargol innunctions and anti-streptococcic serum might be made. The results obtained with the latter in Dr. Chrobak's clinic were very favourable—even better than those of the operations performed by Dr. Latzko. In the clinic amongst 225 cases not treated with serum there were 27 deaths, whilst amongst 246 cases where the serum was used only 13 deaths occurred—i.e., a mortality of 5·28 per cent. During the last two years 55 patients suffering from peritonitis have been operated upon by Dr. Latzko. Of these 28 were cases of free diffuse inflammation and 27 were cases of circumscribed inflammation; of the former 28 patients 9 recovered and 19 died, while of the latter 27 patients 23 recovered and only 4 died. His results were therefore fairly favourable.

Removal of a Tumour of the Hypophysis Cerebri through the Nose.

An interesting account of one of the rarest operations was given by Professor Schloffer of Innsbruck at a recent meeting of the Medical Society. The patient was a man, aged 30 years, who was so weak that only a quick and not extensive operation could be attempted. The symptoms were constant headache, anæmia, bitemporal hemianopsia, and lately a very unusual symptom presented itself—namely, the rapid disappearance of all the hair on the body except a few hairs on the pubes and on the chin. Examination by x rays revealed the presence of a tumour of the hypophysis; the sella turcica was manifestly enlarged, being of about the size of a walnut, and its contents cast a shadow similar to that of the neighbouring brain tissue. The patient complained of unbearable pains in the head and neck, his sexual power was almost entirely lost, and he was prepared to undergo any operation which gave a prospect of relief. The first stage of the operation consisted in freeing the whole nose by the method of Bruns and turning it to the right side. All the turbinated bones were removed and the septum was excised, the resulting profuse hæmorrhage being checked by plugging. The inner wall of the left orbit was removed until the optic foramen was reached; the inner walls of the antrum of Highmore and the nasal process of the upper jaw were broken away without loss of blood. The ethmoidal sinus was then cleared out and the sphenoidal cavity was opened. By careful measurement it was ascertained that the operator had actually reached the sella turcica, for the difficulty lay in this, that it was essential for a good result to know whether the cavity exposed was really the sphenoidal cavity, diminished by the enlarged sella turcica, or whether the ethmoidal labyrinth was still present. An x-ray photograph showed the distance between the root of the nose and the sella turcica to be six centimetres but as x-ray photographs are usually enlarged copies of the original the actual distance was computed to be 5·3 centimetres, and at this depth, after perforating another lamina of bone, a bluish tumour was visible; it was very soft and friable, and although carefully removed parts of it were lost in the blood. The greatest part of the tumour (about four-fifths) was extirpated in this way, but the remainder could not be got at without damaging the dura mater, so it was left behind. A large quantity of cerebro-spinal fluid escaped at the end of the operation. The cavity in the sella turcica was plugged with gauze dipped in balsam of Peru, a similar gauze drain was packed on the base of the skull, and both drains were led out towards the nose, which was replaced and carefully fixed in position with sutures. The after-history was uneventful. For the first few days cerebro-spinal fluid came out at the tip of the nose every few minutes. The headache completely vanished. The drains remained *in situ* for nine days and were not renewed. Except for an attack of erysipelas no trouble intervened and recovery was complete by the fifth week after the operation. The hemianopsia was the same as before, but the patient could enjoy life again. A curious fact was that his hair began to grow again everywhere; the explanation was not easy, perhaps the hypertrophy of the hypophysis produced an over-action of the organ, which was probably detrimental to the growth of hair. The examination of the removed parts proved them to be simply an enlarged hypophysis. Notable features of the operation were the unexpected ease with which the gland was reached, the small amount of hæmorrhage in the latter stages, and the absence of post-operative meningitis. No more than 20 cases of operation for such conditions are at present known and this is supposed to be the only successful one.

May 27th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Epileptic Colony.

The first epileptic colony in Australia was opened by Lady Talbot just before she left Victoria. It is situated at Clayton on a block of 165 acres of fertile land presented by Mr. Mason. Accommodation will be afforded for 70 patients, at a cost of about £7000. It is intended to make the institution so far as possible self-supporting from the start, using the land for farming and raising bees, silk, and flowers.

Hospital Matters.

During a recent inquest on the body of a child who had previously attended at the Melbourne Children's Hospital it was disclosed that it was the custom of the resident medical staff to give death certificates on information obtained from the hospital records. The coroner said it was a practice that should be stopped.—At a recent meeting of the committee of the Western Suburbs Cottage Hospital (Sydney) attention was drawn to several cases which were admitted to the hospital on the recommendation of outside medical practitioners, though the patients were well able to afford private treatment. A resolution was passed asking the coöperation of residents in seeing that only deserving cases among the poor of the district are sent in for treatment.—Tenders have been accepted for the erection of a consumption block at the Hospital for Incurables, Waterfall, New South Wales.

Pollution of Sydney Water-supply.

The Sydney Water and Sewage Board has endeavoured to get the public works department to take measures to prevent pollution of the Sydney water-supply from the Cataract River, but the department is not inclined to do anything as the Government analyst was of opinion that the water was not so bad as Dr. E. S. Stokes, the board's medical officer, stated. Dr. Stokes never said that it was injurious to health but that it contained a large amount of organic matter. The board passed a resolution at its last meeting earnestly requesting the Minister of Public Works to allow the board to clear away as much as possible of the vegetable matter in the catchment area.

Nuisance from George's River, Liverpool.

Dr. W. G. Armstrong, medical officer of health of the metropolitan district, New South Wales, has furnished a report on the alleged nuisance at Liverpool caused by pollution of the George's River. He finds that the river is grossly polluted, mainly from wool-washing, and that wastes therefrom should be satisfactorily purified before they are admitted to the river and that wool-washing and fell-mongering should be proclaimed as noxious trades.

Aid to Friendly Societies.

The Premier of New South Wales announced at a demonstration given by the Grand Lodge of the Independent Order of Oddfellows on April 9th that the Government proposed to aid the friendly societies by giving—

1. One-third of the cost after 12 months' sickness of all members under the age of 65 years, or being women, under the age of 60.
2. To pay the whole cost of sick pay for all members over the age of 65 in the case of men, and over the age of 60 in the case of women. The cost to the State not to exceed 3*s.* 4*d.* per week under 65, nor 5*s.* per week over 65—

subject to the following conditions:—

(*a*) That sickness fund is proved solvent by valuation and that a pro-rata reduction be made on certificate of registrar of friendly societies, according to degree of insolvency; (*b*) where no previous valuation and degree of insolvency unascertained, half rates payable until first valuation.

Medical attendance cost to be paid for all members above 65 (females 60). Trustees of society to pay subvention into proper funds and to render adjustment vouchers to Government. Registrar of friendly societies to tabulate and certify as to sickness. Payment conditioned on due observance of requirements under Friendly Societies Acts. Friendly societies may provide in their rules for raising moneys for purchase of annuity grants for their members. Any surplus appearing on valuation of friendly society may be devoted to the purchase of Government annuity for its members.

Action against a Dentist.

A dentist was the defendant in a recent action in Sydney to recover £100 compensation for injuries alleged to have been received by the plaintiff through negligence of the defendant in extracting her teeth. The plaintiff had a number of teeth extracted under an anæsthetic. She subsequently became very ill with lung trouble and finally coughed up a tooth four months afterwards. The judge said the evidence clearly showed that the plaintiff's illness was due to the defendant's action and negligence and gave a verdict for £75.

April 23rd.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—A smoking concert in connexion with this association will be held at the Café Monico, Piccadilly Circus, W., on Thursday evening next, June 6th, at 9 P.M. Members can obtain tickets from Mr. E. Canny Ryall, 77, Harley-street, London, W.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on May 17th at Caxton House, Westminster, Dr. F. H. Champneys being in the chair. The Board considered charges as stated after their names against the following midwives whose names were ordered to be erased. Sarah Scott, that at a confinement she did not send for a medical man, the patient being ill with a high temperature. Mary Broxson, that at a confinement she did not send for a medical man on the occurrence of rigor. Ellen Lang, that at a confinement the perineum being ruptured she did not send for a medical man. Mary Lewin, that at a confinement she did not send for a medical man, the patient suffering from puerperal fever. Emma Applegate, that at a confinement the child when born being apparently in a dying condition she did not send for a medical man. Bridget Duffy, that at a confinement, the child being stillborn and no registered medical practitioner being in attendance, she failed to notify the occurrence to the local supervising authority. Mary Elliott, that at a confinement she was intoxicated. Mary Dunn, that she had been convicted of keeping a disorderly house. Martha Ann Laurance, that at a confinement she was guilty of negligence and misconduct. Elizabeth Jane Brennand, Charlotte Hales, and Emma Page, that they persistently refused to provide themselves with the appliances and antiseptics required by Rule E, 2. After charges had been considered against the following midwives they were censured by the Board: Ellen Pomfret, Catherine Johnson Waugh, and Louisa Wood. After charges against the following midwives had been considered they were cautioned by the Board: Hannah Rhodes, Mary Ann Smith, and Mary Upton.

Obituary.

SIR JOSEPH FAYRER, BART., K.C.S.I., M.D. EDIN., LL.D. EDIN. AND ST. ANDREWS, F.R.C.P. LOND., F.R.C.S. ENG. AND EDIN., F.R.S. LOND. AND EDIN., &C.,

PHYSICIAN-EXTRAORDINARY TO THE KING.

IT is with very great regret that the profession at large, the Indian Medical Service, and a very large circle of personal friends have heard of the passing away of Sir Joseph Fayrer. He died at his residence, Belfield, Falmouth, on Tuesday, May 21st, at the advanced age of 82 years.

Joseph Fayrer was the second son of Robert John Fayrer and Agnes, daughter of Richard Wilkinson, a Lancashire gentleman. His father, who attained to the rank of commander in the Royal Navy, subsequently commanded an Indiaman, for many years sailed in ships of that class, and was one of the pioneers of ocean steam navigation. The distinguished subject of our memoir was born on Dec. 6th, 1824, at Plymouth, where his father and mother were on a visit after one of the former's voyages back from India. He was educated under the Rev. R. Wallace at Dalrymple in Ayrshire, under private tutors, and at a private school at Liverpool. In 1840 he began the study of engineering, but, finding it too mechanical, at the age of 17 years was appointed a midshipman to the *Thames*, one of the fine fleet of steamers of the newly inaugurated West Indian Mail Steam-Packet Service, and in her he went to the West Indies, to Mexico, and to South America. He subsequently sailed with his father on H.M.S. *Tenedos* to Bermuda. On arrival the vessel was detained there as a receptacle for prisoners, as Bermuda was then a convict station. While at Bermuda his future career was determined during an outbreak of yellow fever. Becoming strongly impressed with the importance of the medical profession and seeing how highly it was valued and how great an influence its members exercised for good he determined to study to enter it. He first attended the practice of the naval hospital at Bermuda and in August, 1844, it was decided he should go to London to become a pupil at Charing Cross Hospital. He duly entered the school and registered as a student at the Royal College of Surgeons of England in the winter session of 1844, at the end of which he was awarded a scholarship at his school of £15 a year for two years. At Charing Cross his chief friends among the students were W. G. Hunter, subsequently, as Sir W. Guyon Hunter, surgeon-general of the Bombay army, and T. H. Huxley, the great Professor Huxley. His interest in his hospital never abated and 34 years later he was appointed consulting physician to the hospital and made a life governor. At the end of his second year as a student he was appointed house surgeon at the Westminster Ophthalmic Hospital under Guthrie and Hancock and in July, 1847, passed his examination at the Royal College of Surgeons and was duly enrolled. He became F.R.C.S. Edin. in 1858, M.D. Edin. in 1859, F.R.C.P. Lond. in 1872, and F.R.C.S. Eng. in 1878.

On August 4th, 1847, Sir William Burnett, the Naval Director-General, procured him a commission to H.M.S. *Victory* for service at Haslar Hospital, and accordingly he went to Portsmouth and was placed on the books of the *Victory*, where among his comrades was Dr. Andrew Clark, afterwards the President of the Royal College of Physicians of London. After a few weeks of ordinary duty, in October he was permitted to resign his commission temporarily in order that he might accompany Lord Mount-Edgcumbe on his travels. With Lord and Lady Mount-Edgcumbe he travelled through France, Germany, and Italy. While with them at Palermo political troubles commenced—the Sicilians were in opposition to the Neapolitan Government and before long broke out into open revolution. Together with his friend, Dr. Valentine Mott, he attended to, and did all he could for, the wounded, and obtained his first experience of gunshot wounds. While at Rome in January, 1849, he underwent the examination and received the degree of M.D. Returning to England he held for a few months an appointment in the Ordnance Medical Department, an appointment as assistant surgeon in Bengal, and on June 29th, 1850, he left Gravesend in the *Camperdown*, an East Indiaman, for Calcutta in medical charge of recruits for regiments in India. He arrived at Fort William on Oct. 9th and commenced his Indian service. His first appointment was to the civil station of Cherra Poonjee, whence he was soon ordered to Dacca, which at that time was extremely unhealthy, to take over medical charge of the 74th Bengal Native Infantry. He found on arrival that, with the exception of a few men for orderly work, all the sepoys at headquarters were in hospital; he gained at this time his first experience of cholera.

In 1852 he was selected as one of the field assistant surgeons to accompany the Bengal Division of the Burmah force. When it was decided to send a force up the river on the way to Rangoon to destroy the Thilawa stockade he asked permission to accompany the troops and was ordered to join the war steamer *Phlegethon*; he subsequently landed to escalade the stockade and was present at the spiking of the guns and destruction of the stockade by fire. At the taking of Rangoon, having obtained permission, he landed and formed a field hospital in a poongie-house, near to the White House picket, which was of the greatest service not only for the wounded but to the sufferers from sunstroke. After the city was in our possession, in addition to his other duties, he had those of civil surgeon of Rangoon assigned to him. For his services in Burmah he was transferred to serve under the Indian Foreign Office and was appointed residency surgeon at Lucknow. The offer of the appointment was made to him in an autograph letter signed "Dalhousie," in which the Governor-General explained that he had kept it vacant as the best medical appointment in his gift to bestow it upon the assistant surgeon who should be found to have rendered the most approved services during the war with Burmah. His designation was "Residency Surgeon, Superintendent of the King's Hospital, and Post-master." Colonel Sleeman was at the time the Resident but towards the end of 1854 he fell ill and Colonel Outram assumed the duties. Shortly before this change Fayrer was appointed an Honorary Assistant Resident and thus had political combined with his other duties. The time had come when effect was to be given to one of the articles of Lord Dalhousie's creed, "the extinction of independent provinces within our dominion." The Oudh Government had been so corrupt, despite all warnings, as to have forfeited all claim to further consideration, and Outram was sent to bring this state of things to a conclusion. Early in 1856 the annexation of Oudh, the last important act of Lord Dalhousie's administration, was carried out in detail by Lord Canning's orders, and Outram, anxious to provide for the old Residency officers, recommended that Dr. Fayrer should be made Deputy Commissioner of Lucknow, but the Governor-General wrote suggesting that as Dr. Fayrer had done well in his profession it was a pity to give it up, and that if he chose to continue in his present office he would guarantee his allowances and privileges. He accepted the suggestion and selected the designation of "Civil Surgeon of Lucknow and Superintendent of all charitable institutions." His new appointment dated from March 20th, 1856. During the succeeding months he reorganised the arrangements of the post-office which was then extended over the whole province.

Then came the Indian Mutiny and he was one of the principal actors during those dark days in the Lucknow Residency. He was one of the foremost men of action during the siege and defence from June 30th to the time of the first relief by Havelock and Outram on Sept. 25th, 1857, and during the continuation of the siege till the final relief by Sir Colin Campbell on Nov. 17th, 1857. After the evacuation of the Residency he with others made a forced march to Cawnpore to relieve Wyndham, who was engaged with the Gwalior rebels, and then proceeded to Allahabad where they sojourned in the fort. During the siege of Lucknow, when Sir Henry Lawrence proposed to remove the ladies and children to the Mutchi Bhowan, thinking they would be safer, Dr. Fayrer opposed the suggestion on hygienic grounds in the strongest terms and it soon became known that the last stand was to be made in the Residency. On the eventful day, July 2nd, when Sir Henry Lawrence was mortally wounded, Dr. Fayrer was one of those who tenderly carried his friend to the doctor's bungalow, where he was placed on a bed in the deep front verandah, from which he made an affecting leave-taking, adjuring his staff never to surrender or to treat with the enemy, and to do everything possible to protect the women and children, and, speaking most humbly of himself and all that he had done, he expressed a desire that the only epitaph on his tomb should be, "Here lies Henry Lawrence who tried to do his duty." The notes made by Dr. Fayrer during the siege are very circumstantial

SIR JOSEPH FAYRER, BART., K.C.S.I., M.D., LL.D. EDIN. AND ST. ANDREWS, F.R.C.P. LOND., F.R.C.S. ENG. AND EDIN., F.R.S. LOND. AND EDIN., &c.

PHYSICIAN EXTRAORDINARY TO THE KING.

and thrilling and extracts from them are freely quoted in his "Recollections." During the siege Dr. Fayrer received a severe contusion of the leg from a spent bullet and his eldest son, then an infant, was slightly wounded in the leg by a fragment of shell.

On the suppression of the mutiny Fayrer embarked with his family in March, 1858, from Calcutta, and during his furlough in England studied at the University of Edinburgh with a view to taking the M.D.; this he did after a special examination in March, 1859. In the January of the same year he was elected a Fellow of the Royal Society of Edinburgh. Early in 1859 a vacancy having occurred in the chair of surgery in the Medical College, Calcutta, by the resignation of Professor O'Shaughnessy, the post was offered to Dr. Fayrer while still on furlough and was duly accepted. He returned to India, landed on April 29th, 1859, and at the age of 34 years took up his appointment as professor of surgery in the Medical College and first surgeon to the College Hospital, and thus commenced the second part of his Indian career. In the following year he was given the additional medical charges of the Lower Military Orphan School and of the Mysore princes. In January, 1861, he was elected a member of the Council of the Asiatic Society of Bengal and shortly afterwards a Fellow of the University of Calcutta. In 1863 he was elected a member of the Senate of the University and President of the Faculty of Medicine. In January, 1867, he was appointed President of the Asiatic Society and delivered an address on taking his seat. In this capacity he wrote to the Government recommending that a scientific mission should be sent to Abyssinia and to the Nicobar Islands and proposed a scheme for a zoological society and gardens in Calcutta, which was recommended to be carried out.

On Lord Mayo's arrival on Jan. 12th, 1869, he invited Dr. Fayrer to become his surgeon, which offer he accepted for as long a time as the Viceroy should remain in Calcutta. He at that time submitted a long memorandum upon the native hospital for Lord Mayo's information and was frequently consulted by him on all medical matters connected with the service or the local hospitals. It was about this time that Dr. Fayrer was promoted to the rank of surgeon-major and was appointed consulting surgeon to the Howrah General Hospital. On Dec. 29th, 1869, at a Chapter of the Star of India held at Calcutta, in which the Duke of Edinburgh was invested as a Grand Commander of the Star of India, Dr. Fayrer rode with the other Companions of the Order, having been made a Companion the previous year. On Jan. 1st, 1870, the Viceroy invited him to accompany the Duke of Edinburgh in his travels through the North-west of India. His Royal Highness subsequently made him his physician in ordinary. In the March of the same year he was made honorary physician to the Queen. At this time he was investigating the nature of the poisons of the ophiophagus elaps, the different species of bungarus, and of the salt-water snakes. The results of his experiments were sent home in the rough to his friend Dr. Francis C. Webb, in London, who put them into the form of a book, which was afterwards published by the Government. An acknowledgment of Dr. Webb's work is made in the introduction to the volume, which is entitled the "Thanatophidia of India." This great work, which was dedicated to the ill-fated Viceroy, was the result of his extensive experimental study into the action of snake-poison. Dr. Fayrer's attention had long been fixed on this matter owing to the appalling mortality amongst natives from this cause. The book was magnificently produced and illustrated by beautiful plates, mostly drawn by native members of the Calcutta School of Art. Dr. Fayrer also devoted much attention to the means of checking the loss of native life and property from the ravages of carnivorous animals.

Early in 1873, a year after Lord Mayo's assassination in the Andaman Islands, Dr. Fayrer prepared for a long absence from India, his health having suffered from the climate. During his furlough he was elected a Fellow of the Royal College of Physicians of London and with Lauder Brunton began a series of investigations into the nature and action of snake-poison. In the same year he was appointed a member of the Medical Board at the India Office, of which Sir Ranald Martin was the president. In November, 1873 Sir Ranald Martin sent in his resignation as president and Dr. Fayrer was offered the appointment by Lord Salisbury, Secretary of State for India. He retired from the active list of the Indian army as a deputy surgeon-general, with a pension of £1 a day, and on Dec. 8th took his seat as president. He was also appointed a member of the Senate of the Army Medical School and a little later a member of the Army Sanitary Committee. He was gazetted a surgeon-general with local rank, which rank was ultimately confirmed on his retirement from the India Office.

In March, 1875, General Probyn interviewed him about the Prince of Wales's projected visit to India; the Prince had expressed a wish that Dr. Fayrer should accompany him, and Lord Salisbury desired to know if he would undertake the duty. He did so with pleasure and wrote a memorandum for the Queen and for Lord Salisbury on the Indian climate. In April he visited the Prince at Sandringham and in August he was commanded by the Queen to go to Osborne, when he reassured Her Majesty on the safety of the expedition and undertook the full responsibility that it entailed. The Prince with his suite left London on Oct. 9th and embarked on the *Serapis* at Brindisi on the 16th. Of the great and memorable tour through India an interesting account is given in Dr. Fayrer's "Recollections," where he tells of the careful way in which the tour was arranged on his advice so as to avoid cholera and other dangers due to climatic causes. When at Lucknow he took the opportunity of showing the Prince the shot-riddled remnants of that house which 18 years before he had so heroically helped to defend. It was at Dholepore, on the return from visiting the rock-fortress of Gwalior, that the Prince told him that a telegram had come to the Viceroy from the Queen saying that he (together with Probyn and Browne) was to be made a Knight Commander of the Star of India. His Royal Highness subsequently held a Chapter of the Order at Allahabad and invested him with the insignia. They left Bombay on March 13th and on the return journey visited Cairo, Malta, Gibraltar, and Madrid where they were received by King Alfonso. On May 10th the Prince presented Sir Joseph Fayrer with some valuable souvenirs of the expedition, among them a gold bracelet set with diamonds, with his portrait, for Lady Fayrer. On May 11th the *Serapis* entered Portsmouth Harbour and on the following day he attended the drawing-room with his wife, when all the suite were presented to Her Majesty by the Prince. His name also appeared in that day's *Gazette* as Honorary Physician to the Prince of Wales. In 1879 his journal while with the Prince was published for private circulation.

In April, 1877, Sir Joseph Fayrer was selected as one of the 15 new Fellows of the Royal Society. In conjunction with Dr. (now Sir) Lauder Brunton he had read a paper before the society on the Physiological Action of the Poison of Naja Tripudians which is recorded in the Proceedings; he became a member of the council in 1895. In 1880 he was chosen by the Secretary of State for War to succeed Mr. Busk as examiner in anatomy and physiology at the examination for admissions to the Medical Services, an appointment he held for some years. In the November of 1882 he was elected a governor of Guy's Hospital and later a governor and consulting physician to the Italian Hospital in London. During this period he had an extensive consulting practice which was naturally largely amongst Anglo-Indians. In the August of 1883 he was deputed to represent the Indian Government at the International Congress at Amsterdam. He there read a paper, written conjointly with the late Sir Joseph Ewart, in French, on the Treatment of Tropical Diseases in Temperate Climates. In the May of the next year he commenced giving clinical lectures at Charing Cross Hospital upon Liver Abscess and Tropical Diarrhœa. It was in the same year that the Prince of Wales invited him to be a Royal Commissioner for the Indian and Colonial Exhibition to be held in 1886. In May and June he represented India both technically and diplomatically at the International Cholera Congress held at Rome, and in December he represented the Royal College of Physicians, and the University of Edinburgh at the tercentenary of Galileo at Padua, in the great hall of whose University he addressed the assembly in Italian. The University conferred on him the honorary degree of Doctor of Philosophy. On his retirement from the India Office the officers of the Medical Services, at the suggestion of Major W. W. Webb, I.M.S., who acted as honorary secretary to the movement, invited him to sit for his portrait to be placed in the mess at Netley. It was painted by Sydney Hall in 1896 and was unveiled by Lord Wolseley. On Jan. 8th, 1895, he attended his last board at the India Office and on the 12th retired with a superannuation allowance of £300 a year. Later he was accorded a good service pension of £100 a year. In January, 1896, the Prime Minister informed him that the Queen had conferred a baronetcy on him in recognition of the position which he had attained in his profession and of his long services.

Sir Joseph Fayrer was a prolific writer. In addition to the publications already mentioned, there came from his pen the following works and articles of note: "Clinical Surgery in India" (1866); "Osteomyelitis and Septicæmia" and the "Nature of Visceral Abscess" (1867); "Fibrinous Coagula in the Heart and Pulmonary Artery as a Cause of Death after Surgical Operations" (1867); "Clinical and Pathological Observations in India" (1873); "Tropical Diseases" (his Lettsomian lectures and other papers on cognate subjects), (1881); "The Climate and Fevers of India" (his Croonian lectures at the College of Physicians of London), (1882); "Venom, Effects of: Venomous Animals" (Quain's "Dictionary of Medicine," 1882); "Epidemiology of Cholera" (1888); "Sunstroke," "Climate," and "Fevers of India" (Allbutt's "System of Medicine," 1894); "On Preservation of Health in India" (1894); "Sir Ranald Martin" (1897); "The Hill Stations of India as Health Resorts" (*British Medical Journal*, 1900); "Recollections of my Life" (1900); "Tropical Abscess of Liver" (Murchison's "Lectures on Diseases of the Liver," third edition); "Liver Abscess"; "Tropical Diarrhœa" and "Sunstroke" (Davidson's Hygiène of Warm Climates); and "Natural History of the Tiger." He was also an admirable linguist and he devoted much of his spare time to languages. In India Burmese, Urdu, and Persian, the last being the language of official correspondence with the Court of Lucknow, occupied his attention; in Europe the study of Italian was a favourite relaxation, while he was a good French scholar. Sir Joseph Fayrer was associated with most of the learned societies of the day. We have already recorded his election as a Fellow of the Royal Society and also as a Fellow of the Royal Society of Edinburgh. While a student he was elected a Fellow of the Royal Geographical Society, a corresponding member of the Zoological, and a member of the Hakluyt Societies. He subsequently became a Fellow, member of the council, and Vice-President of the Zoological Society, a Fellow of the Royal Medical and Chirurgical Society, and a member of the Pathological Society, to the membership of the council of which he was elected in 1880. He was also at one time President of the Medical Society and was President of the Epidemiological Society during the years 1879 and 1880. In 1885 he was elected a corresponding member of the Academy of Medicine of France and later was promoted to be a foreign associate. In the same year he was made an honorary corresponding member of the Société d'Hygiène Publique of Paris and an honorary member of the Royal Academy of Medicine of Rome. He was also a foreign corresponding member of the Royal Academy of Science of Lisbon and a Fellow of the Academy of Science and College of Physicians of Philadelphia. Taking a great interest in sanitary science, he became President of the Association of Medical Men holding Sanitary Science Diplomas, afterwards called "The Royal Society of Public Health." In 1878 he received the honorary degree of LL.D. from the University of Edinburgh and 12 years later the University of St. Andrews honoured him with a similar degree.

Sir Joseph Fayrer's interest in education was continued throughout his life. In addition to his direct interest as a teacher in the Calcutta and Charing Cross Medical Schools he took a lively interest in the welfare of many other educational establishments. He was a governor of Wellington College and of Epsom College of which latter institution he was appointed a member of the council in 1877 and subsequently chairman; to this College he had previously handed over as a thank-offering, all his prize money and batta for Burmah, and the batta and 12 months' prize-money for the defence of Lucknow. For many years the welfare of the Army Medical School at Netley greatly occupied his time and thoughts. He distributed the prizes on more than one occasion and was a regular attendant at the meetings of the senate and at the gatherings which closed the different sessions of the school as long as he remained in office. After his retirement he visited the school and addressed the young officers at the close of the sessions as often as his health permitted him. He for years gave a prize.

Sir Joseph Fayrer will be remembered in after years as a great official and as one with whom his professional calling was ever first. In Calcutta he was deservedly regarded as a great surgeon, and this reputation might have been continued and extended in this country, but having in 1872 become a Fellow of the Royal College of Physicians of London etiquette forbade his undertaking any work of the kind. In 1881 he delivered the Lettsomian lectures on Dysentery. He was the Croonian lecturer in 1882 and a member of the council of the College of Physicians in 1886. He was a consulting physician and governor of Charing Cross Hospital. The medical officers of the military and naval services owe a great debt of gratitude to Sir Joseph Fayrer, and by them his name will ever be held in special honour; by his own life and actions he consistently supported the dignity of the medical officer and his calling, as, indeed, he did that of the whole profession of medicine.

Sir Joseph Fayrer was all his life through a keen sportsman, which proclivity was inherited from, and fostered by, his father. In India he killed a great number of tigers and much other game, especially in the Terai, where he made expeditions in 1855, 1857, and again with the Prince of Wales. After his retirement from India almost every year he shot and fished at Dunrobin with the Duke of Sutherland and at St. Mary's Isle with Lord Selkirk. In 1877 he wrote a paper for *Nature* upon the subject of the towering of birds, in which he ascribed it to asphyxia from bleeding of the lungs, and not necessarily from injury to the head, as commonly supposed. In the following year he gave a lecture on the destruction of life in India by snakes and wild animals at the Society of Arts. His paper not only dealt with the mortality but with the animals that caused it. For it he was awarded a silver medal by the society. After his retirement from active work he passed his time between his house in Devonshire-street and Falmouth, of which latter place he had a great opinion as a winter resort. At Falmouth he devoted much time to boating and deep-sea fishing and up to the last he maintained a keen and active interest in these sports.

In appearance Sir Joseph Fayrer presented the physical characteristics of the sturdy Briton and his manners were in keeping with his looks. Although so frequently the companion of Royal personages and a *persona grata* in Courts he in no respect fulfilled the popular idea of the courtier. He was gently dignified, blunt, humorous, and no great respecter of persons. An admirable talker, he required drawing out, and it was especially to the questions of young men that he responded most sympathetically. The record of his life shows that he possessed intense personal bravery, both physical and moral, and his career as well as his qualities of mind and body tended to make him take a broad and wide view of things. There was nothing of the learned professor about him. He was superlatively well read in medical and general literature, and excellently versed in that knowledge which cannot be gained from books—knowledge of human nature—but his attitude in argument and general conversation was a modest and unobtrusive one; it was impossible not to feel that he spoke only when he was quite sure of his ground, and then never for effect but always on the side of justice or humanity. The record of his work and public services which we have given shows that the world has lost in Sir Joseph Fayrer a distinguished man of science and a successful and energetic man of affairs; those who knew him are regretting a friend of the kind that cannot be replaced.

Sir Joseph Fayrer married in the cantonment church at Lucknow, on Oct. 4th, 1855, Bethia Mary, the eldest daughter of Brigadier-General Andrew Spens, who was then commanding the troops there, and by her, who survives him, had a family of six sons and two daughters. The marriage proved an exceedingly happy one and to his wife "in remembrance of 45 years spent together" in 1900 he dedicated the "Recollections of my Life." To her in her bereavement and to her children we offer our sincerest sympathy and these "in memoriam" notes of a life in all respects well spent. His eldest son Robert Andrew Fayrer predeceased him and his second son, Lieutenant-Colonel Joseph Fayrer, R.A.M.C., succeeds to the baronetcy. The next son is a colonel in the Ghoorkas and the youngest is a member of the Royal Army Medical Corps.

JOSEPH GROVES, B.A., M.B. LOND., L.R.C.P. LOND., J.P.,

MEDICAL OFFICER OF HEALTH OF THE ISLE OF WIGHT RURAL DISTRICT.

BY the death of Dr. Joseph Groves one of the foremost practitioners and certainly the foremost local champion of public health is lost to the Isle of Wight. Dr. Groves's death was due to overwork and the recrudescence of an old lung trouble which dates back, as to its genesis, quite 40 years. A King's College man in the days of William Fergusson, Richard Partridge, Robert Bentley Todd, and George Johnson, his early training was associated with the teaching of a day when public health as a science had not yet come into its kingdom. Yet so young did his mind remain and so receptive was he to each "new thing" that official recognition of public health as the foremost need of the hour found Dr. Groves fully equipped for the office which he sought and held as rural medical officer of health of the important district of the Isle of Wight for the last 25 years, and though his private practice was large it will be by the work of that official position that he will be chiefly remembered in the island; indeed, it would be well-nigh impossible to forget that work. Devotion hardly describes his toil therein and fearlessness and independence are almost inadequate words whereby to paraphrase his public conduct. And he did not lack honours, though he did not greatly seek them; indeed, like the Shunamite, he seemed to value most the appreciation of his "own people," but other praise and commendation were his for all that. He was the vice-president of the Section of State Medicine when the British Medical Association met in Canada and was intimately identified for many years with much of the work of that association. He was also a past President of the Incorporated Society of Medical Officers of Health. He was a London graduate, held many appointments at King's College Hospital in his post-qualified days, saw the cholera epidemic of 1866 through (with Conway Evans), then travelled for a short time and finally settled down in the island of which he was a son—coming as he did of an old Vectian family—and lived and toiled and died at his beloved Carisbrooke on May 21st. In local life and local endeavour his name was always first and his influence ever a good influence. To name all he did for those "sons of men" whose local contemporary he was would hardly be understood or appreciated outside the environment in which his tender sympathy was exercised and felt. He leaves one of those blanks in the life of his late home which make men pause and wonder as to how any other man will now fill it. Dr. Groves was aged 68 years and was unmarried.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Wm. B. Fletcher, formerly professor of neurology and mental diseases in the University of Indiana.—Dr. O. F. Roler, formerly professor of midwifery in the North-Western Medical School, Chicago.—Dr. Wm. H. Drummond, professor of forensic medicine in Bishop's College, Montreal.—Dr. H. Jordan, professor of midwifery in the University of Cracow.—Dr. Theodor von Jürgensen, professor of medicine in the University of Tübingen, aged 67 years. He was the author of a manual of Special Pathology and Therapeutics and of a considerable number of papers and articles in medical encyclopædias on acute infectious diseases and heart and lung affections.—Dr. Ivan Nasiloff, formerly professor of operative medicine in the St. Petersburg Military Medical Academy.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in May the following candidates passed in the subjects indicated:—

Surgery.—R. Beesley (Sections I. and II.), Manchester; H. S. Burnell-Jones (Section II.), Cardiff, Leeds, and London Hospital; S. A. Mahmood, Middlesex Hospital; E. Moir (Sections I. and II.), Manchester; C. C. Morrell (Section II.) and G. H. Rodolph (Sections I. and II.), London Hospital; and S. H. Watton (Section II.), Manchester.

Medicine.—E. V. Connellan (Section I.), Bristol; J. Creo, Belfast; F. M. Cunningham (Section I.), Royal Free Hospital; R. Spears (Sections I. and II.), University College Hospital; and E. E. C. Vollet (Sections I. and II.), Paris.

Forensic Medicine.—C. L. Driscoll, Charing Cross Hospital; H. E. Middlebrooke, London Hospital; and E. H. Paterson, Guy's Hospital.

Midwifery.—H. W. Phillips, Manchester; W. P. Pinder, Leeds; E. W. Squire, St. Mary's Hospital; and G. L. Walker, Leeds.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: H. S. Burnell-Jones, S. A. Mahmood, E. Moir, C. C. Morrell, R. Spears, and E. W. Squire.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

F. J. Cahill, L.R.C.S.I., &c.; B. H. Dickson, L.R.C.S.I., &c.; T. W. A. Fullerton, B.Ch., &c., R.U.I., Major I.M.S.; P. E. Hayden, L.R.C.S.I., &c.; H. Stokes, B.Ch., &c., Univ. Dub.; and P. D. Sullivan, L.R.C.S.I., &c.

The following candidates have passed the primary part of the Fellowship examination:—

W. F. O'Connor, B.Ch., &c., R.U.I.; Miss E. R. Benjamin, H. Charles, F. J. Colgan, E. A. Gregg, P. M. J. Power, and R. S. White.

HIS MAJESTY THE KING has sent a gift to the Royal Waterloo Hospital for Children and Women, S.E., in the shape of a quantity of cast linen.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual meeting and conference were held at 11, Chandos-street, London, W., on May 22nd, Dr. Leslie Roberts, the President, being in the chair. Upon the completion of the usual business formalities an oration was delivered by Professor Dr. Lassar of Berlin, who chose for his subject, "The Relationship of Dermatology to the Other Branches of Medical Science." The lecture was illustrated by a series of beautifully coloured lantern slides. The annual dinner of the society was held the same night at the Imperial Restaurant, the distinguished orator of the afternoon being the chief guest.

UNIVERSITY OF CAMBRIDGE.—Mr. Adam Sedgwick has been reappointed a manager of the Balfour Fund for Animal Morphology.—A course in Systematic Botany will be given during the long vacation in the new botany school, beginning on July 6th.—It is proposed to establish a university diploma in anthropology for advanced students and graduates who have pursued the subject under the direction of the Board of Anthropological Studies.—An exhibition of £50 a year for two years is offered by Emmanuel College for an advanced student pursuing a course of research in the University. The student will have to begin residence in October, 1907.

DONATIONS AND BEQUESTS.—By the will of Mrs. Stephanie of Hampstead the Middlesex Hospital will benefit by a sum of £1050, and Charing Cross Hospital, the North London Hospital for Consumption, the Victoria Hospital for Children, Guy's Hospital, St. Mary's Hospital, and the Hampstead Hospital and Nursing Institute will each receive £1000. £500 each have been left to the Kilburn Dispensary, Brompton Hospital for Consumption, Royal Hospital for Incurables, and the French Hospital, while the Surgical Aid Society and the Freidenheim Hospital will receive £250 each for charitable purposes. Subject to other legacies, the testatrix left the residue of her estate to the following hospitals: the North London Hospital for Consumption, Charing Cross Hospital, Victoria Hospital for Children, Middlesex Hospital, Guy's Hospital, St. Mary's Hospital, and Hampstead Hospital. The amount available for charitable purposes will be about £16,000.—Mr. William Young of Peebles has by will bequeathed land the value of which is about £12,000 to the town council of Peebles for the purpose of founding a sanatorium for the treatment of pulmonary tuberculosis.

THE IMPROVEMENT OF ROME.—Mr. Morgan, the British Consul, in his annual report, just received at the Foreign Office, states that after a somewhat protracted period of economic depression Rome has awakened to a new existence. Within the brief period of 37 years the city has been almost rebuilt, and by comparing a map of 1870 with one of the present time it can be seen at a glance that its topography has altered considerably. The population at present is believed to be about 520,196, the number of foreigners being nearly 10,000, including some 1800 British. The pretty small towns and villages near Rome are now served by a regular electric tramway service. The country is being gradually opened up and symptoms of activity are everywhere discernible. The two railway stations in Rome, known as Termini and Trastevere, are to be shortly connected by means of a direct line. The death-rate has decreased considerably since 1871, as will be seen from these figures: 1871, 41·8 per 1000 inhabitants; 1875, 33·9; 1879, 25·1; 1883, 24·3; 1887, 22·8; 1891, 20·9; 1895, 19·2; 1900, 19·0; and 1905, 20·6. The former scourge of the district of Rome was malaria. Improved sanitation and the measures everywhere adopted in order to avoid infection through the dreaded mosquito have largely contributed to reduce the rate of mortality from that disease. The deaths from malaria were 189 in 1893, 189 in 1895, 73 in 1897, 87 in 1899, 76 in 1901, 48 in 1903, and 65 in 1905. The Vice-Consul at Civita Vecchia the publications already mentioned, there came from his pen the following works and articles of note: "Clinical Surgery in India" (1866); "Osteomyelitis and Septicæmia" and the "Nature of Visceral Abscess" (1867); "Fibrinous Coagula in the Heart and Pulmonary Artery as a Cause of Death after Surgical Operations" (1867); "Clinical and Pathological Observations in India" (1873); "Tropical Diseases" (his Lettsomian lectures and other papers on cognate subjects), (1881); "The Climate and Fevers of India" (his Croonian lectures at the College of Physicians of London), (1882); "Venom, Effects of: Venomous Animals" (Quain's "Dictionary of Medicine," 1882); "Epidemiology of Cholera" (1888); "Sunstroke," "Climate," and "Fevers of India" (Allbutt's "System of Medicine," 1894); "On Preservation of Health in India" (1894); "Sir Ranald Martin" (1897); "The Hill Stations of India as Health Resorts" (*British Medical Journal*, 1900); "Recollections of my Life" (1900); "Tropical Abscess of Liver" (Murchison's "Lectures on Diseases of the Liver," third edition); "Liver Abscess"; "Tropical Diarrhœa" and "Sunstroke" (Davidson's Hygiene of Warm Climates); and "Natural History of the Tiger." He was also an admirable linguist and he devoted much of his spare time to languages. In India Burmese, Urdu, and Persian, the last being the language of official correspondence with the Court of Lucknow, occupied his attention; in Europe the study of Italian was a favourite relaxation, while he was a good French scholar. Sir Joseph Fayrer was associated with most of the learned societies of the day. We have already recorded his election as a Fellow of the Royal Society and also as a Fellow of the Royal Society of Edinburgh. While a student he was elected a Fellow of the Royal Geographical Society, a corresponding member of the Zoological, and a member of the Hakluyt Societies. He subsequently became a Fellow, member of the council, and Vice-President of the Zoological Society, a Fellow of the Royal Medical and Chirurgical Society, and a member of the Pathological Society, to the membership of the council of which he was elected in 1880. He was also at one time President of the Medical Society and was President of the Epidemiological Society during the years 1879 and 1880. In 1885 he was elected a corresponding member of the Academy of Medicine of France and later was promoted to be a foreign associate. In the same year he was made an honorary corresponding member of the Société d'Hygiéne Publique of Paris and an honorary member of the Royal Academy of Medicine of Rome. He was also a foreign corresponding member of the Royal Academy of Science of Lisbon and a Fellow of the Academy of Science and College of Physicians of Philadelphia. Taking a great interest in sanitary science, he became President of the Association of Medical Men holding Sanitary Science Diplomas, afterwards called "The Royal Society of Public Health." In 1878 he received the honorary degree of LL.D. from the University of Edinburgh and 12 years later the University of St. Andrews honoured him with a similar degree.

Sir Joseph Fayrer's interest in education was continued throughout his life. In addition to his direct interest as a teacher in the Calcutta and Charing Cross Medical Schools he took a lively interest in the welfare of many other educational establishments. He was a governor of Wellington College and of Epsom College of which latter institution he was appointed a member of the council in 1877 and subsequently chairman; to this College he had previously handed over as a thank-offering, all his prize money and batta for Burmah, and the batta and 12 months' prize-money for the defence of Lucknow. For many years the welfare of the Army Medical School at Netley greatly occupied his time and thoughts. He distributed the prizes on more than one occasion and was a regular attendant at the meetings of the senate and at the gatherings which closed the different sessions of the school as long as he remained in office. After his retirement he visited the school and addressed the young officers at the close of the sessions as often as his health permitted him. He for years gave a prize.

Sir Joseph Fayrer will be remembered in after years as a great official and as one with whom his professional calling was ever first. In Calcutta he was deservedly regarded as a great surgeon, and this reputation might have been continued and extended in this country, but having in 1872 become a Fellow of the Royal College of Physicians of London etiquette forbade his undertaking any work of the kind. In 1881 he delivered the Lettsomian lectures on Dysentery. He was the Croonian lecturer in 1882 and a member of the council of the College of Physicians in 1886. He was a consulting physician and governor of Charing Cross Hospital. The medical officers of the military and naval services owe a great debt of gratitude to Sir Joseph Fayrer, and by them his name will ever be held in special honour; by his own life and actions he consistently supported the dignity of the medical officer and his calling, as, indeed, he did that of the whole profession of medicine.

Sir Joseph Fayrer was all his life through a keen sportsman, which proclivity was inherited from, and fostered by, his father. In India he killed a great number of tigers and much other game, especially in the Terai, where he made expeditions in 1855, 1857, and again with the Prince of Wales. After his retirement from India almost every year he shot and fished at Dunrobin with the Duke of Sutherland and at St. Mary's Isle with Lord Selkirk. In 1877 he wrote a paper for *Nature* upon the subject of the towering of birds, in which he ascribed it to asphyxia from bleeding of the lungs, and not necessarily from injury to the head, as commonly supposed. In the following year he gave a lecture on the destruction of life in India by snakes and wild animals at the Society of Arts. His paper not only dealt with the mortality but with the animals that caused it. For it he was awarded a silver medal by the society. After his retirement from active work he passed his time between his house in Devonshire-street and Falmouth, of which latter place he had a great opinion as a winter resort. At Falmouth he devoted much time to boating and deep-sea fishing and up to the last he maintained a keen and active interest in these sports.

In appearance Sir Joseph Fayrer presented the physical characteristics of the sturdy Briton and his manners were in keeping with his looks. Although so frequently the companion of Royal personages and a *persona grata* in Courts he in no respect fulfilled the popular idea of the courtier. He was gently dignified, blunt, humorous, and no great respecter of persons. An admirable talker, he required drawing out, and it was especially to the questions of young men that he responded most sympathetically. The record of his life shows that he possessed intense personal bravery, both physical and moral, and his career as well as his qualities of mind and body tended to make him take a broad and wide view of things. There was nothing of the learned professor about him. He was superlatively well read in medical and general literature, and excellently versed in that knowledge which cannot be gained from books—knowledge of human nature—but his attitude in argument and general conversation was a modest and unobtrusive one; it was impossible not to feel that he spoke only when he was quite sure of his ground, and then never for effect but always on the side of justice or humanity. The record of his work and public services which we have given shows that the world has lost in Sir Joseph Fayrer a distinguished man of science and a successful and energetic man of affairs; those who knew him are regretting a friend of the kind that cannot be replaced.

Sir Joseph Fayrer married in the cantonment church at Lucknow, on Oct. 4th, 1855, Bethia Mary, the eldest daughter of Brigadier-General Andrew Spens, who was then commanding the troops there, and by her, who survives him, had a family of six sons and two daughters. The marriage proved an exceedingly happy one and to his wife "in remembrance of 45 years spent together" in 1900 he dedicated the "Recollections of my Life." To her in her bereavement and to her children we offer our sincerest sympathy and these "in memoriam" notes of a life in all respects well spent. His eldest son Robert Andrew Fayrer predeceased him and his second son, Lieutenant-Colonel Joseph Fayrer, R.A.M.C., succeeds to the baronetcy. The next son is a colonel in the Ghoorkas and the youngest is a member of the Royal Army Medical Corps.

JOSEPH GROVES, B.A., M.B. LOND., L.R.C.P. LOND., J.P.,

MEDICAL OFFICER OF HEALTH OF THE ISLE OF WIGHT RURAL DISTRICT.

BY the death of Dr. Joseph Groves one of the foremost practitioners and certainly the foremost local champion of public health is lost to the Isle of Wight. Dr. Groves's death was due to overwork and the recrudescence of an old lung trouble which dates back, as to its genesis, quite 40 years. A King's College man in the days of William Fergusson, Richard Partridge, Robert Bentley Todd, and George Johnson, his early training was associated with the teaching of a day when public health as a science had not yet come into its kingdom. Yet so young did his mind remain and so receptive was he to each "new thing" that official recognition of public health as the foremost need of the hour found Dr. Groves fully equipped for the office which he sought and held as rural medical officer of health of the important district of the Isle of Wight for the last 25 years, and though his private practice was large it will be by the work of that official position that he will be chiefly remembered in the island; indeed, it would be well-nigh impossible to forget that work. Devotion hardly describes his toil therein and fearlessness and independence are almost inadequate words whereby to paraphrase his public conduct. And he did not lack honours, though he did not greatly seek them; indeed, like the Shunamite, he seemed to value most the appreciation of his "own people," but other praise and commendation were his for all that. He was the vice-president of the Section of State Medicine when the British Medical Association met in Canada and was intimately identified for many years with much of the work of that association. He was also a past President of the Incorporated Society of Medical Officers of Health. He was a London graduate, held many appointments at King's College Hospital in his post-qualified days, saw the cholera epidemic of 1866 through (with Conway Evans), then travelled for a short time and finally settled down in the island of which he was a son—coming as he did of an old Vectian family—and lived and toiled and died at his beloved Carisbrooke on May 21st. In local life and local endeavour his name was always first and his influence ever a good influence. To name all he did for those "sons of men" whose local contemporary he was would hardly be understood or appreciated outside the environment in which his tender sympathy was exercised and felt. He leaves one of those blanks in the life of his late home which make men pause and wonder as to how any other man will now fill it. Dr. Groves was aged 68 years and was unmarried.

Surgery.—R. Beesley (Sections I. and II.), Manchester; H. S. Burnell-Jones (Section II.), Cardiff, Leeds, and London Hospital; S. A. Mahmood, Middlesex Hospital; E. Moir (Sections I. and II.), Manchester; C. C. Morrell (Section II.) and G. H. Rodolph (Sections I. and II.), London Hospital; and S. H. Watton (Section II.), Manchester.

Medicine.—E. V. Connellan (Section I.), Bristol; J. Cree, Belfast; F. M. Cunningham (Section I.), Royal Free Hospital. R. Spears (Sections I. and II.), University College Hospital; and E. E. C. Vollet (Sections I. and II.), Paris.

Forensic Medicine.—C. L. Driscoll, Charing Cross Hospital; H. E. Middlebrooke, London Hospital; and E. H. Paterson, Guy's Hospital.

Midwifery.—H. W. Phillips, Manchester; W. P. Pinder, Leeds; E. W. Squire, St. Mary's Hospital; and G. L. Walker, Leeds.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: H. S. Burnell-Jones, S. A. Mahmood, E. Moir, C. C. Morrell, R. Spears, and E. W. Squire.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

F. J. Cahill, L.R.C.S I., &c.; R. H. Dickson, L.R.C S.I., &c.; T. W. A. Fullerton, B.Ch., &c., R.U.I., Major I.M.S.; P. E. Hayden, L.R.C.S.I., &c.; H. Stokes, B.Ch., &c., Univ. Dub.; and P. D. Sullivan, L.R.C.S I., &c.

The following candidates have passed the primary part of the Fellowship examination:—

W. F. O'Connor, B.Ch., &c., R.U.I.; Miss E. R. Benjamin, R. Charles, F. J. Colgan, E. A. Gregg, P. M. J. Power, and R. S. White.

HIS Majesty the King has sent a gift to the Royal Waterloo Hospital for Children and Women, S.E., in the shape of a quantity of cast linen.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual meeting and conference were held at 11, Chandos-street, London, W., on May 22nd, Dr. Leslie Roberts, the President, being in the chair. Upon the completion of the usual business formalities an oration was delivered by Professor Dr. Lassar of Berlin, who chose for his subject, "The Relationship of Dermatology to the Other Branches of Medical Science." The lecture was illustrated by a series of beautifully coloured lantern slides. The annual dinner of the society was held the same night at the Imperial Restaurant, the distinguished orator of the afternoon being the chief guest.

UNIVERSITY OF CAMBRIDGE.—Mr. Adam Sedgwick has been reappointed a manager of the Balfour Fund for Animal Morphology.—A course in Systematic Botany will be given during the long vacation in the new botany school, beginning on July 6th.—It is proposed to establish a university diploma in anthropology for advanced students and graduates who have pursued the subject under the direction of the Board of Anthropological Studies.—An exhibition of £50 a year for two years is offered by Emmanuel College for an advanced student pursuing a course of research in the University. The student will have to begin residence in October, 1907.

DONATIONS AND BEQUESTS.—By the will of Mrs. Stephanie of Hampstead the Middlesex Hospital will benefit by a sum of £1050, and Charing Cross Hospital, the North London Hospital for Consumption, the Victoria Hospital for Children, Guy's Hospital, St. Mary's Hospital, and the Hampstead Hospital and Nursing Institute will each receive £1000. £500 each have been left to the Kilburn Dispensary, Brompton Hospital for Consumption, Royal Hospital for Incurables, and the French Hospital, while the Surgical Aid Society and the Freidenheim Hospital will receive £250 each for charitable purposes. Subject to other legacies, the testatrix left the residue of her estate to the following hospitals: the North London Hospital for Consumption, Charing Cross Hospital, Victoria Hospital for Children, Middlesex Hospital, Guy's Hospital, St. Mary's Hospital, and Hampstead Hospital. The amount available for charitable purposes will be about £16,000.—Mr. William Young of Peebles has by will bequeathed land the value of which is about £12,000 to the town council of Peebles for the purpose of founding a sanatorium for the treatment of pulmonary tuberculosis.

THE IMPROVEMENT OF ROME.—Mr. Morgan, the British Consul, in his annual report, just received at the Foreign Office, states that after a somewhat protracted period of economic depression Rome has awakened to a new existence. Within the brief period of 37 years the city has been almost rebuilt, and by comparing a map of 1870 with one of the present time it can be seen at a glance that its topography has altered considerably. The population at present is believed to be about 520,196, the number of foreigners being nearly 10,000, including some 1800 British. The pretty small towns and villages near Rome are now served by a regular electric tramway service. The country is being gradually opened up and symptoms of activity are everywhere discernible. The two railway stations in Rome, known as Termini and Trastevere, are to be shortly connected by means of a direct line. The death-rate has decreased considerably since 1871, as will be seen from these figures: 1871, 41·8 per 1000 inhabitants; 1875, 33·9; 1879, 25·1; 1883, [illegible]·3; 1887, 22·8; 1891, 20·9; 1895, 19·2; 1900, 19·0; and 1905, 20·6. The former scourge of the district of Rome was malaria. Improved sanitation and the measures everywhere adopted in order to avoid infection through the dreaded mosquito have largely contributed to reduce the rate of mortality from that disease. The deaths from malaria were 189 in 1893, 189 in 1895, 73 in 1897, 87 in 1899, 76 in 1901, 46 in 1903, and 65 in 1905. The Vice-Consul at Civita Vecchia says that the position of that bathing resort is gradually improving. The waterworks are now ready and a plentiful supply of good drinking water is available. As a scarcity of water was the chief reason why visitors shunned Civita Vecchia during the summer months it is hoped that the town will again become the favourite watering-place of the Romans.

THE COLONIAL NURSING ASSOCIATION.—On the invitation of the Duke and Duchess of Westminster a meeting of the Colonial Nursing Association will be held on June 14th at 3.30 P.M. at Grosvenor House. Princess Henry of Battenberg, the patroness of the association, has signified her intention of being present, and Lord Ampthill will preside. The speakers will include the Right Hon. Austen Chamberlain, M.P., the Right Hon. Sir George T. Goldie, and Sir Francis Hopwood.

LONGEVITY.—Mrs. Honor Coleman of Cleeve. Somerset, is perhaps the oldest woman in England, having recently attained the remarkable age of 107 years. Her mother was a centenarian, as was her grandmother who lived to the age of 101 years, while her daughter who lives with her is nearly 80 years of age.—The Rev. John Aldis of Beckington, Somerset, entered his 100th year on May 12th.—Mrs. Metherell of Tavistock, Devonshire, attained the 103rd anniversary of her birthday on May 21st.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.—The report of this society for 1906 was presented at the general meeting of the members held on May 23rd. At the end of 1906 there were 2488 members, being an increase of 59 during the year, all being male members of the medical profession or Licentiates of Dental Surgery practising in the United Kingdom. The funds increased by more than £12,000 and now amount to £208,357. The amount paid in sickness benefit during the year was £11,494, being the largest yet disbursed in one year. The annual premium income in this branch is £15,302. The management expenses are low and there is a large balance to the credit of the management fund—viz., £13 469. We should have preferred to see the interest on this sum set out more clearly but it is no doubt included in the investment fluctuation reserve fund which amounts to £12,966. A full list of the assets is given and it is interesting to notice the large amounts invested in Australian stocks.

THE PREVENTION OF PULMONARY TUBERCULOSIS—A conference of representatives of the metropolitan borough councils on the question of taking measures to limit the spread of pulmonary tuberculosis will be held at the Paddington town hall on Thursday, June 6th. Notice of the following motion has been given by Councillor W. J. Nolan of Paddington:—

> (a) That it is desirable that the notification of pulmonary tuberculosis (consumption) should be compulsory. (b) That application be made to the Local Government Board for an order to be made—(i.) To include pulmonary tuberculosis (consumption) among the diseases to be notified under Section 55 of the Public Health (London) Act, 1891; and (ii.) to extend the provisions of the following sections of the above Act to pulmonary tuberculosis (consumption)—Section 60, cleansing and disinfecting of premises, &c.; Section 61, disinfection of bedding, &c.; Section 62 infectious rubbish thrown into ash-pits, &c., to be disinfected; Section 63, penalty on letting houses in which infected persons have been lodging; Section 64. penalty on persons letting houses making false statements as to infectious disease; Section 65, penalty on ceasing to occupy house without disinfection or notice to owner or making false answer.

And further—

> That the President of the Local Government Board be asked to receive a deputation from the conference in support of the resolution (if adopted).

The propositions include a further motion on behalf of the Poplar borough council:—

> That, in the opinion of this conference, it is desirable, in order to limit the spread of pulmonary tuberculosis, provision should be made for public inspection and control at its several sources of the milk-supply of London.

We have before us an excellent report issued to the Paddington public health committee at the beginning of this year by Dr. Reginald Dudfield, medical officer of health of the borough. In this he gives a good account of the etiology of, and rational means of combating, tuberculosis, and adduces cogent reasons in favour of compulsory notification of at least the pulmonary form of the disease in order to limit its spread. The pamphlet would appear to have borne good fruit and although we think that the evidence in favour of compulsory notification is at present insufficient to justify its general adoption we hope that the deliberations of the borough councils' representatives may have beneficial results; the awakening of public interest in these matters of national health is an excellent sign of the times, and the exertions of medical officers of health cannot be more profitably directed than in instructing the public on their grave importance.

THE ROYAL WATERLOO HOSPITAL.—The Festival Dinner Committee has announced that the net proceeds of the dinner at the Savoy Hotel on May 14th last would exceed £1100.

HOLIDAY GUIDES.—The municipal authorities of several of the English health resorts now issue free guides to their respective towns, which can be obtained from the town clerks by forwarding on a post-card a request for a copy. These guides are admirable productions both from the literary and pictorial points of view, and are valuable aids in the selection of a suitable holiday resort. We have received specimens of the guides issued by the local authorities of Bournemouth, Hastings, Leamington Spa, Southwold, Tenby, and Weymouth.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Compensation for Industrial Diseases

THE Departmental Committee on Compensation for Industrial Diseases has just issued an elaborate and interesting report. This Committee was appointed by the Home Secretary in August, 1906, to inquire and to report "what diseases and injuries other than injuries by accident are due to industrial occupations, are distinguishable as such, and can properly be added to the diseases enumerated under the third schedule of the Workmen's Compensation Act, 1906." The members of the Committee were Mr. HERBERT SAMUEL, the Parliamentary Under Secretary of State for the Home Department (chairman), Professor T. CLIFFORD ALLBUTT of Cambridge; Mr. H. H. CUNYNGHAME, C.B., Assistant Under Secretary, Home Office; and Dr. T. M. LEGGE, medical inspector of factories. After prolonged investigation the Committee recommends that a large number of industrial diseases should be added to the third schedule of the Act, thus entitling workpeople who contract them in the course of their employment to compensation.

It may be explained that Section 8 of the Workmen's Compensation Act permits the Home Secretary to include additional diseases in the third schedule from time to time. Compensation is to be paid to a workman who is found to be suffering from a scheduled disease, and if the workman has been employed in any process mentioned in the schedule opposite to that disease, then, in the ordinary course, the disease shall be deemed to be due to the nature of that employment unless the employer proves the contrary. The members of the Committee have summarised their recommendations in a tabulated form.

If the Home Secretary acts on the advice of the Departmental Committee compensation to workpeople incurring these diseases in the ordinary nature of their employment will be payable in exactly the same manner as in the case of anthrax, lead poisoning or its sequelæ, mercury poisoning or its sequelæ, arsenic poisoning or its sequelæ, and ankylostomiasis incurred in mining. These are the diseases which already appear in the third schedule of the Act. In recommending the numerous additions to the schedule the Departmental Committee mentions that some of the diseases are seldom seen by medical men and occasionally difficulties of diagnosis may arise. It thinks it most desirable that the medical referees, who will be appointed to adjudicate on medical points in disputed cases, should be specialists with particular knowledge and experience of these diseases.

The Whitsuntide Holidays.

The House of Lords resumed on Tuesday last after the Whitsuntide holidays. The House of Commons re-assembled on Thursday, May 23rd.

The Butter and Margarine Bill.

One of the Standing Committees of the House of Commons had the Butter and Margarine Bill under consideration on Monday. Sir EDWARD STRACHEY, who represents the Board of Agriculture in the House of Commons, induced the committee to accept amendments reclassifying the substances dealt with in the Bill. As originally drafted the Bill took cognisance of pure butter, milk-blended butter, butter substitutes or imitation butters, and margarine. Sir EDWARD STRACHEY explained that the effect of his amendment was to have one butter substitute only and that to be what was now known as milk-blended butter. All other imitation butters were to come under the definition of margarine. Some discussion arose on the moisture clause which limits the proportion of water in butter and margarine to 16 per cent. and in butter substitutes to 24 per cent. Sir FRANCIS LOWE moved an amendment to limit the proportion of water in milk-blended butter to 16 per cent., on the ground that a higher percentage of moisture in it would lead to the perpetration of fraud on the consumer. In the course of the discussion Sir EDWARD STRACHEY intimated that the regulations of the Board of Agriculture would be framed to prevent this substance being sold under the title of milk-blended butter. Whilst they did not object to the sale of an article demanded by the public, yet they objected to the name "butter" being used in the description of it. This amendment had not been voted upon when the committee rose for the day.

Purity of Milk Supplies (Scotland) Bill.

Mr. WATT has introduced into the House of Commons a Bill to insure the purity of the milk-supplies of the rural and urban districts of Scotland. It was read a first time.

HOUSE OF COMMONS.

THURSDAY, MAY 23RD.

Municipal Milk Depôts.

Mr. RIDSDALE asked the President of the Local Government Board, whether he could state the cost of installation and of working and the receipts of any municipal milk depôts for which figures might be available.—Mr. J. BURNS gave a long and elaborate written reply relating to municipal milk depôts in Battersea, Lambeth, Woolwich, Bradford, Burnley, Liverpool, St. Helens, Ashton-under-Lyne, and Dukinfield. In the case of Battersea the cost of the installation was set down at £659. For the year ended March, 1907, the receipts were estimated at £795 and the expenditure at £1259. The cost of adapting premises in Lambeth for a milk depôt and of fittings and utensils was £881. During last year the receipts from it were £286, whilst the expenditure was £430. In Woolwich the cost of installation was £663, but the department had only been open since November. At Bradford the cost of machinery, fixtures and fittings was £444 and for the year ended March, 1907, the receipts were £1874 and the expenditure £1868. The Burnley depôt was opened in 1905, the installation costing £390. For the last financial year the receipts came to £425, but the expenditure was £640. In the case of Liverpool the costs of installation were included under the expenditure of the year. The figures of receipts and expenditure were as follows:—

Year.	Receipts.	Expenditure.
	£	£
1901	518	2000
1902	1535	4315
1903	2231	4259
1904	1676	3634
1905	1644	3632
1906	1250	3206

At St. Helens the cost of installation was returned at £391, and the depôt had been working for seven or eight years. In the year ended March, 1907, the receipts amounted to £78. The expenditure for the same period was £256. At Ashton-under-Lyne the receipts of the municipal milk depôt during the last financial year amounted to £449, whilst the expenditure on it came to £559. At Dukinfield the milk depôt was closed after an existence of two years.

FRIDAY, MAY 24TH.

The Vaccination Bill.

Mr. J. A. PEASE (on behalf of the President of the Local Government Board) formally moved the second reading of the Vaccination Bill.

Sir JOHN BATTY TUKE moved the rejection of the measure. He said that he objected to the Bill because it was illogical. It would neither meet the views of the anti-vaccinationists nor of the vaccinationists and it would afford increased opportunities for evading the law, and this would become a danger to the public health. The Bill, if it became law, would have the effect of increasing the anti-vaccination agitation and also the number of the extremists. It would not affect the honest objector to vaccination, for he was at present willing to sacrifice himself and to take trouble to vindicate his opinions. It was unluckily the case that even the honest conscientious objector dragged in his train a large number of persons who had no settled convictions on the subject of vaccination, such as ignorant parents and guardians. This class, he feared, would soon become a dangerous element. Soon it would be declared that the Vaccination Acts had become dead. At present small-pox was in abeyance, but as sure as the sun would rise to-morrow small-pox would reappear in an unprotected community. A large portion of it would be unvaccinated and when an epidemic of small-pox broke out there would be a rush of persons to be vaccinated and then it would be found that the local authorities were unable to meet the demand. He often wondered whether the antivaccinationists had ever seen an epidemic of small-pox among an unprotected community. If they had gone through this experience, as he had done on more than one occasion, they could not fail to realise the horrible condition of things that ensued from the outbreak of small-pox. With few exceptions all civilised countries had adopted vaccination with great advantage. In these circumstances was the Government justified in bringing forward a measure which sapped at the very foundations of the Vaccination Acts? The President of the Local Government Board was, at the instance of a small section of the community, throwing the responsibility on the shoulders of the illiterate but in the long run the responsibility for what would happen must fall on the right honourable gentleman himself. It must, however, be admitted that the time had come for a revision of the working of the law on this subject. He therefore suggested that the present Bill should be abandoned and a small representative committee appointed to consider the subject. Such a committee, he hoped, might arrive at a modus vivendi, which would be the foundation of a Bill acceptable to all sides.

Mr. CAVE seconded the motion for the rejection of the Bill. He believed that the Bill would not effect a settlement of the vaccination question. The measure was regarded by anti-vaccinationists as an instalment leading up to the larger policy of the abolition of the vaccination law. It was beyond controversy that vaccination was a real protection against small-pox and against a fatal termination to the attack of the disease when it did occur. The effect of the Bill was to make it much easier to obtain exemptions. If they made the process of obtaining these exemptions as much easier as the Bill proposed they would have persons in all classes either from mere carelessness or from unwillingness to undergo trouble, signing the proposed statutory declaration. The result would be that the number of exemptions would be very seriously increased. By passing the Bill they would be running the great risk of exposing the public to a great increase of a very dangerous and loathsome disease.

Mr. BURNS (the President of the Local Government Board) said that he had earlier in the session promised certain alterations in respect to vaccination. The first thing was a reduction in the cost which in recent years had been unduly inflated. Only in the course of the present week he had issued a Vaccination Order carrying out to the full the pledge he had given on this point. Then he had promised some form of statutory declaration in place of the existing exemption certificate. The Bill now under consideration gave effect to that promise. He had further promised that the Government would do its best to secure uniformity of action by the magistrates pending the adoption of the other measures promised, and the Home Secretary had issued a circular advising magistrates not only to be more discreet but also more reasonable and uniform in the administration of the law relating to exemptions. He had further undertaken that the Government would consider the possibility of transferring the whole administration of vaccination from the boards of guardians to the public health authorities. However, until the Royal Commission which was inquiring into the Poor-law reported he could not carry out, as he should like to do, the transfer. Finally, he promised that they would consider the question of suspending vaccination in early infancy and postponing it until a later period of life. However, until the two sets of opinion represented respectively by the honourable Member for Sleaford (Mr. Lupton) and the honourable Member for Edinburgh and St. Andrews Universities (Sir John Batty Tuke) reconciled themselves more amicably on other phases of vaccination, he could not see a way to redeem this promise. Proceeding, the right honourable gentleman said that it must be a subject of congratulation to everybody that the terrible scourge of small-pox was diminishing, and it was gratifying to know that in the year 1906 there were in England and Wales only 21 deaths from this disease, and that in London, with a population of 5,000,000, there was not a single death from the disease. The object of the Bill now under debate was to bring about an alteration in the manner of obtaining exemption from penalties for omitting to have a child vaccinated by substituting a statutory declaration for the certificate of conscientious objection required by the Act of 1898. Those who were responsible for inserting the word "satisfies" in Section 2 of that Act were to some extent responsible for the necessity of amending it now. The difficulty of administering the section had been foreseen by certain Members, whose predictions had been justified by the event. It was now admitted, even by opponents of the present Bill, that some of the magistrates had exceeded their powers. The Home Office had at last been compelled to issue circulars asking magistrates to do their duty in a way that would not give offence to applicants for exemption. Another matter of complaint under the present law was that in order to obtain a certificate of exemption parents were compelled to attend the court under a quasi-criminal aspect. The Bill substituted for the present process a simple statutory declaration before a commissioner for oaths or a justice of the peace. The parent who made such a declaration would be exempted from the stamp duty, which the Chancellor of the Exchequer had generously consented to waive. He would, however, have to pay a small fee required by the Statutory Declarations Act, 1835, which varied from a shilling to eighteenpence. It might be urged that this Bill would make the way of the conscientious objector too easy. Similar predictions were made in 1898, but, as a matter of fact, the conscientious objections since that date had remained practically stationary. It was the case that the Royal Commission had contemplated a statutory declaration of some kind and desired to call the parent before the local authority. That procedure would be more inconvenient and irritating than appearing before a justice of the peace, or a commissioner for oaths, or a stipendiary magistrate. A suggestion had been made that recourse for the purposes of the statutory declaration should be had to the registrar rather than to the commissioner for oaths and the magistrate. He saw no reason for adopting that suggestion, as the registrar was in no sense connected with vaccination and it was undesirable to create any more vested interests with regard to it. In the administration of the law with respect to vaccination they ought not to have an officer who might be supposed to be increasing his professional business by taking these declarations. It was exceedingly important to satisfy all parties that the commissioners for oaths, the magistrates, and the justices of the peace who would take these declarations under the Bill should be regarded as neutral persons and that they received their fees for the declaration and for no other purpose. In his belief, the nuisance which had grown up under the Bill of 1898 was intolerable and could not be allowed to continue. He also believed that the useful little Bill now under consideration would go a long way to remove the grievance of the conscientious objector. He trusted that it would receive the hearty sympathy of the House.

Mr. PICKERSGILL thought that the Government ought to have gone further in its legislation and have removed the neglect of vaccination altogether from the purview of the criminal law.

Sir HENRY CRAIK said that it was impossible for him to remain silent on this question in view of the fact that a large proportion of his constituents, as medical graduates of the Universities of Aberdeen and Glasgow, were interested in the matter from the point of view of medical science. He felt that the Bill was a concession to prejudice and ignorance. It left no discretion whatever in the hands of the commissioner for oaths and the justice of the peace. It substituted a secret signature for a statement of conscientious objection in the light of publicity with the aid which publicity gave to distinguish between ignorance, carelessness, thoughtlessness, or prejudice and a conscientious objection to vaccination. He feared that there would be a very serious diminution in the percentage of vaccination. Surely it was unwise to yield to the pressure of those who were in opposition to the fixed conclusions of the great mass of scientific medical opinion.

Sir FREDERICK BANBURY also opposed the second reading of the Bill. It was with regret that he saw the President of the Local Government Board yielding to the pressure of the anti-vaccinationists. This concession to them would only be made the jumping ground for further demands. The Bill, in his view, was a step towards the abolition of compulsory vaccination.

The House then divided, when there voted:—

For the rejection of the Bill, 14; against, 122; majority against rejection, 108.

Sir John Batty Tuke's amendment being thus defeated, the motion for the second reading of the Bill was agreed to without a division.

MONDAY, MAY 27TH.

Reported Remedy for the Opium Habit.

Mr. Pike Pease asked the Secretary of State for India whether his attention had been called to the statement by Mr. L. Wray, director of Museums of the Federated Malay States, in regard to the new anti-opium remedy and to the results obtained from its use in Selangor; also to the statement that at the Weld-road establishment of the Selangor Anti-Opium Society, in Kuala Lumpur, from Nov. 16th to 23rd last about 400 patients had reported that they were completely cured of the habit of opium smoking; and whether in these circumstances His Majesty's Government would appoint a committee to investigate the matter.—Mr. Churchill said, in reply: I shall answer this question instead of the Secretary of State for India. I have not seen the statements to which the honourable member refers, but the High Commissioner for the Federated Malay States reports that there is considerable conflict of opinion with regard to the alleged cure. The Government analyst of the Straits Settlements has been unable to find any special constituent in the plant or plants from which the decoction is prepared and it is said that the same effects have been produced by a strong infusion of tea. A further analysis is now being conducted at the Imperial Institute, and pending a report on the results it would be premature to consider the question of appointing a committee.

Motor Accidents in London.

In reply to Mr. Cathcart Wason, Mr. Gladstone (the Home Secretary) said: The number of accidents in the metropolis known to the police to have been caused in the streets by motor-cars, motor-cycles, and motor-omnibuses during the six months ended April 30th last is 4451. Of these accidents, personal injury resulted in 1175 cases and fatal injury in 41 cases.

TUESDAY, MAY 28TH.

The Inspection of Irish Pork.

Mr. Watt asked the Chief Secretary to the Lord Lieutenant of Ireland whether he would insure that all carcasses of swine slaughtered in Ireland for export were inspected in accordance with the recommendation of the Local Government Board—namely, that the presence of tuberculous deposit in any degree should involve seizure of the whole carcass and organs; and, if the carcasses and organs could not be inspected by competent inspectors in Ireland, would he take steps to prevent the flesh being exported to Scotland for human food.—Mr. Birrell replied: The Local Government Board for Ireland has on two occasions brought the recommendation mentioned in the question to the notice of local authorities in Ireland, but the Board has no power to enforce its adoption. The inspection of meat intended for human food is a matter for the local authorities themselves. The Board has no power to prohibit the export of meat. I have no information that unfit meat is exported to Scotland, but if it be suggested that such is the case I imagine that the Scottish local authorities would have power to deal with the matter. Upon that point, however, my honourable friend should address the Secretary for Scotland.

Schools and the Dissemination of Disease.

Mr. Whitehead asked the President of the Board of Education whether his attention had been drawn to the fact that when individual children were kept away from an elementary school by order of the medical officer of health their absence, by reducing the average attendance, reduced the Parliamentary grant; whether he was aware that reduction in such circumstances operated hardly upon poor districts and discouraged proper precautions against the spreading of disease; and whether steps could be taken to assimilate the administration of elementary schools in this particular to that prevailing in secondary schools where no loss of Parliamentary grant was sustained through absence caused by illness.—Mr. McKenna answered: The absence of individual children, whatever be the cause, necessarily reduces the average attendance of the school, but I do not think any serious loss of grant results from exclusion under medical authority—for example, the exclusion of 40 children for a week would only involve a loss of about £2 to the local education authority. The method of computing average attendance will, of course, be one of the questions demanding careful consideration in connexion with any scheme for reorganising the system of grants, but I have grave doubts whether the system at present in force in secondary schools could be applied without very considerable modifications to elementary schools.

WEDNESDAY, MAY 29TH.

The National Physique.

Captain Faber asked the Secretary of State for the Home Department whether there were any statistics to show that the national physique had bettered or deteriorated during the last ten years, in addition to the findings of the Departmental Committee recently issued.—Mr. Gladstone replied: I am not aware of the existence of any general official statistics on this subject. I think the deficiency is to be regretted.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.*

Annand, W. Fraser, M.D., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Physician to the Staffordshire General Infirmary, Stafford.

Bradley, Frederick H., M.B., Ch.B. Edin., has been appointed Senior House Surgeon at the Liverpool Stanley Hospital.

Colyer, H. C., M.R.C.S., L.R.C.P. Lond., L.D.S., has been appointed House Surgeon at the Royal Dental Hospital of London and School of Dental Surgery.

Cooper, R. W. C., L.D.S. R.C.S. Eng., has been appointed House Surgeon at the Royal Dental Hospital of London and School of Dental Surgery.

Costouros, J., M.D., L.M., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

Crosby, Harry Main, M.B., C.M. Edin., has been appointed Honorary Surgeon to the General Hospital, Stroud (Gloucestershire).

Cuttriss, W. A., L.D.S. R.C.S. Eng., has been appointed House Surgeon at the Royal Dental Hospital of London and School of Dental Surgery.

Fleury, K. F., L.R.C.P. & S. Irel., has been appointed Medical Officer for the Riverstown Dispensary District of Birr, King's County, Ireland.

Jubb, Archibald, M.D. Glasg., has been appointed Extra Honorary Physician to the Royal Hospital for Sick Children, Glasgow.

Morris, William David Joseph, M.R.C.S., L.R.C.P. Edin., L.S.A., has been appointed Medical Officer to the Cardiff Post Office (Eastern District).

Patrick, J. King, M.B., Ch.B. Glasg., has been appointed Extra Honorary Physician to the Royal Hospital for Sick Children, Glasgow.

Russell, W. K., M.B. Glasg., has been appointed Medical Officer and Public Vaccinator for the No. 1. (Ilminster) District by the Chard (Somerset) Board of Guardians.

Sibbald, Ian Graham, M.B., C.M. Edin., has been appointed Medical Officer of Health by the Chard (Somerset) Rural District Council.

Sprawson, F. B., M.R.C.S., L.R.C.P. Lond., L.D.S., has been appointed House Surgeon at the Royal Dental Hospital of London and School of Dental Surgery.

Stevens, Bertram Crossfield, M.S., M.D. Durh., F.R.C.S. Edin., L.R.C.P. Lond., has been appointed Additional Honorary Anæsthetist to the Lancaster Royal Infirmary.

Sutcliffe, P. H., L.D.S. R.C.S. Eng., has been appointed House Surgeon at the Royal Dental Hospital of London and School of Dental Surgery.

Treasure, William Beeson Crawford, M.D. Durh., M.R.C.S., L.S.A., has been appointed Medical Officer to the Cardiff Post Office (Western District).

Vintras, G. C. Louis, M.D. Durh., has been appointed Director of the French Convalescent Home at Brighton and of the Annexe for the Preventive Treatment of Tuberculosis.

Wade, Charles, L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon to the Boscastle (Cornwall) Friendly Society.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ayr District Asylum.—Junior Assistant Physician. Salary £120, with board, apartments, and laundry.

Bethlem Hospital.—Two Resident House Physicians (unmarried) for six months. Salary £50, with apartments, board, and washing.

Bradford Children's Hospital.—House Surgeon. Salary £100.

Bradford Royal Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

Brixton Dispensary.—Resident Medical Officer, unmarried. Salary £150, with apartments, attendance, coal, and gas.

Bury St. Edmunds, West Suffolk General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board and lodging.

Cheltenham General Hospital.—Surgeon-in-Charge of the Branch Dispensary, unmarried. Salary £90 per annum, with board and lodging.

Chesterfield and North Derbyshire Hospital and Dispensary.—Junior House Surgeon. Salary £80 a year, with board, apartments, and laundress.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Medical Officer. Salary £120 per annum, with board, &c. Also Surgeon and Physician to the Out-patients.

Coventry and Warwickshire Hospital.—Junior House Surgeon for six months, renewable. Salary £60 per annum, with rooms, board, washing, and attendance.

Devonport, Royal Albert Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, board, &c.

Dumfries and Galloway Royal Infirmary.—Assistant House Surgeon. Salary £25 per annum, with board and washing.

Egypt.—Sub-Inspector of Ophthalmic Hospitals, unmarried. Salary £500 a year.

Epsom, London County Asylum, Horton.—Fifth Assistant Medical Officer. Salary £150 a year, with board, apartments, and washing.

Guildford, Royal Surrey County Hospital.—Assistant House Surgeon. Salary £50, with board, residence, and laundry.

Halifax Union Poor-law Hospital, Salterhebble.—Resident Medical Officer. Salary £125 per annum, with apartments, rations, and washing.

Her Majesty's Hospital for Children (Dr. Barnardo's Homes), Stepney Causeway, E.—House Surgeon and Resident Medical Officer. Salary £60, with board, lodging, and washing.

Hospital for Sick Children, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, with board and residence. Also Anæsthetist.

Hull, Royal Infirmary.—Casualty House Surgeon. Salary £50, with board and lodging.

Indian Medical Service.—An Examination for not less than 11 Commissions.

Isle of Wight Rural District Council.—Medical Officer of Health. Salary £300 per annum.

Leicester Infirmary.—Assistant House Physician for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

Maidstone, West Kent General Hospital.—Assistant House Surgeon and Anæsthetist, unmarried. Salary £60, with board, lodging, and washing.

Manchester, St. Mary's Hospitals for Women and Children.—Fourth House Surgeon for six months. Salary £25, with board and residence.

Manchester, University of.—Junior Demonstrator of Physiology. Salary £100, rising to £150 per annum.

Newport and Monmouthshire Hospital.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and laundry.

Newcastle-upon-Tyne, City and County of.—Assistant Medical Officer of Health and Resident Medical Officer of the City Hospital for Infectious Diseases, unmarried. Salary £300 per annum, with board, lodging, &c.

Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Salary £20, with apartments, board, and laundry.

North-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—House Physician, also House Surgeon, both for six months. Salaries at rate of £60 per annum, with board, residence, and laundry.

Nottingham General Hospital.—Locum Tenens for three and a half months. Salary £45, with board, lodging, and washing.

Paddington Infirmary and Workhouse.—First Assistant to the Medical Superintendent of the Infirmary and Assistant Medical Officer of the Workhouse, unmarried. Salary £120 per annum, rising to £150, with board, lodging, and washing. Also Second Assistant to the Medical Superintendent of the Infirmary and Medical Officer of the Workhouse, unmarried, for six months. Salary at the rate of £72 per annum, with board, lodging, and washing.

Royal Eye Hospital, S.E.—House Surgeon. Salary £52 10*s.* per annum, with board and residence.

St. Bartholomew's Hospital.—Lectureship in Anatomy.

Salford Royal Hospital.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Throat Hospital, Golden-square, W.—House Surgeon. Salary at rate of £75 per annum, with residence, board, and laundry.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Honorary Anæsthetist.

Walsall and District Hospital.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

West Bromwich District Hospital.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing. Also Senior House Surgeon, unmarried. Salary £110 per annum, with board, residence, and washing.

West London Hospital, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry allowance provided.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Withnell, in the county of Lancaster; at Hemsworth, in the county of York; and at Horsmonden, in the county of Kent.

Births, Marriages, and Deaths.

BIRTHS.

Barlow.—On May 25th, at "Sa Maison," Somersham, Huntingdonshire, the wife of H. Cecil Barlow, M.B., L.R.C.P., M.R.C.S., of a son.

McNeight.—On May 22nd, at Thaxted, Essex, the wife of W. R. P. McNeight, M.D. T.C.D., of a daughter.

Russell.—On May 25th, at Osman House, Fortis Green, N., the wife of J. Dill Russell, F.R.C.S. Eng., of a son.

Schofield.—On May 29th, at 1, Phillimore-gardens, Kensington, the wife of S. Robert Schofield, M.B. Lond., a daughter.

MARRIAGES.

Macsherry—Aubril.—At the Oratory, Birmingham, Maurice Macsherry, L.R.C.P., &c., 72, Summerhill-road, Birmingham, to Valérie Marie Louise Aubril of Summerhill Court, Kingswinford, daughter of Louis Stanislas Aubril, Sartilly, Manche, France.

Riviere—Osler.—On May 22nd, at Rosslyn-hill Chapel, Hampstead, Clive Riviere, M.D., to Henrietta Maria (Hetty), daughter of Thomas Osler, and granddaughter of the late T. Smith Osler of Hampstead.

Stanwell—Gilling.—On May 23rd, at St. John's Parish Church, Chipping Barnet, F. Skey Stanwell, M.D., to Edith Elizabeth, second daughter of Henry R. Gilling, J.P., of Sowerby, Ravenscourt Park, Barnet, Herts.

DEATHS.

Groves.—On May 21st, at his residence, Carisbrooke, Isle of Wight, Joseph Groves, B.A., M.B. Lond., in his 65th year.

Wood.—At Margaret-street, Cavendish-square, W., on May 25th, Caroline Augusta Charlotte, wife of T. Outterson Wood, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A MONSTROUS COUNTER-CLAIM.

At the Greenwich county court on April 19th, before his honour Judge Willis, K.C., Mr. E. Middlebrooke, L.S.A., of Eltham, sued Mr. David T. McCulloch, of 104, Earlshall-road, Eltham, for £3 12*s.* 6*d.*, fee for medical attendance, and the defendant counter-claimed for £50 damages for careless treatment and faulty diagnosis of his wife's illness, alleging that the deceased met her death from this cause. Mr. Mathew (counsel), instructed by the solicitors of the London and Counties Medical Protection Society, appeared for the plaintiff and Mr. Walton (solicitor) for the defendant. The plaintiff's claim being admitted, judgment was entered for him for the £3 12*s.* 6*d.*, and his honour then proceeded to hear the counter-claim. The defendant said that he called in Mr. Middlebrooke to attend his wife in November, 1904. Mr. Middlebrooke proved from his books that he had diagnosed and treated the case as Bright's disease and Dr. John Rice deposed that he had made the same diagnosis independently. The defendant stated that Mr. Middlebrooke had diagnosed "gall-stones and a growth." After hearing the evidence his honour, in giving a judgment in favour of Mr. Middlebrooke, expressed himself in very warm terms on the defendant's conduct in raising such a counter-claim. It was a monstrous claim that should never have been persisted in. He had spoken strongly because there were always base minds ready to entertain any insinuations, but so far as his voice could help he wished it to go forward that Mr. Middlebrooke's treatment of the deceased had been skilful and proper and there was not the slightest evidence to show that any one of the defendant's statements was justified. We are glad to be able to record so trenchant a judicial pronouncement on the impropriety of such preposterous claims against medical men.

THE TREATMENT OF DIABETES.

To the Editors of The Lancet.

Sirs,—Could any of your readers give me the name of any drug that has proved in their experience a "cure" for diabetes? The case is of the obese type and of some duration. The worst symptoms are great depression of spirits, bodily weakness, and constipation.

I am, Sirs, yours faithfully,

May 13th, 1907.

M.B., C.M.

"LEONARD DE BAYER."

An Aberdeen correspondent writes:—

> "The capture of a man wanted by the Liverpool police authorities took place at Aberdeen last week, the arrest having been made through the instrumentality of a letter which appeared last week in The Lancet. In that letter information was given that a young man, 'Leonard de Bayer,' was wanted on a charge of obtaining money by false pretences, he being in the habit of calling at hospitals and upon medical men at their private addresses and under the pretence of being connected with the firm of Bayer Co., Ltd., borrowing money which he did not pay back. A man, about 36 years of age, exactly answering the description published in The Lancet, wearing gold-rimmed eye-glasses and dressed in a frock coat and a silk hat, arrived in Aberdeen on Thursday night. He called on the medical superintendent of the Aberdeen Royal Lunatic Asylum and produced letters of introduction from two well-known medical men in Glasgow. It was too late in the evening, however, to show him the institution. Next day the young man appeared at Marischal College and attended the Giffard lecture by Dr. Hans Dresch, Heidelberg, the well-known embryologist, who was dealing with cells and cell-formation in his course, the Science and Philosophy of the Organism. After the lecture the young man, who represents himself as a Prussian doctor, entered into conversation with the lecturer and with one of the university medical professors, subsequently accompanying the latter to his house in the west-end of the city. The professor stated that he would show the visitor over Marischal College on the following day. The professor's suspicions were aroused when the man declared himself as one of the leading medical men connected with the New York State Asylum and also as associated with the firm of Messrs. Bayer Co., Ltd., combining the professional and commercial interests. Nor did the visitor manifest the interest or knowledge expected of him on being taken through the anatomical museum, although in the anthropological museum he had a good deal to say regarding interesting specimens he had secured while in Bohemia and other countries while "doing Europe" in a motor-car. Subsequently at luncheon in the professor's house, the latter's suspicions were further aroused by the references his guest made to visits paid to eminent and Royal personages and to having been associated with the Thaw trial. Reading The Lancet after luncheon on Sunday afternoon the professor recognised that the man wanted by the Liverpool police might be his guest of the previous day. He telephoned to the house of another medical professor with whom the young man had previously intimated he was to have luncheon that day, and the answers to inquiries revealed

the fact that the visitor was in the garden enjoying a smoke. On THE LANCET'S letter having been read to him over the telephone the other professor was also convinced that the man wanted was enjoying the brilliant sunshine in the garden, peacefully smoking. Subsequently the police were informed from the asylum where the visitor was to have dined in the evening and the man was arrested at his hotel late at night. He passed the bar at the Aberdeen Police-court on Monday and was handed over to the Liverpool authorities."

A NEGLECTED TEXT.

To the Editors of THE LANCET.

SIRS,—In rejoinder to "Soberness" the name Jotham does not mean "Jot" and "Ham" but "Jehovah is upright." Also, when he says that "Jotham ran away, and fled, and went to Beer, and dwelt there," and "They go to Beer because they take to beer as a drink," he apparently does not know that "Beer" meant a "well," and that the well contained good water, as may be seen by Numbers xxi. 16, as follows: "And from thence they went to Beer: that is the well whereof the Lord spake unto Moses, Gather the people together and I will give them water." I learn that some people think that the word "God" in the line "*which cheereth God and man*" should be "gods" as the parable was addressed to the idolatrous Shechemites and that others think the word meant "nobles" or "rich"—i.e., "cheereth rich as well as poor." Yet others find an explanation in the "drink offering unto the Lord," as referred to in Exodus xxix. 40, and Numbers xv. 7. But even *sober* commentators have admitted that "These are strange words." And some have called the parable of the trees the most ancient and beautiful apologue extant.

I am, Sirs, yours faithfully,

May 27th, 1907. CEDAR.

A DIPHTHERIA PATIENT IN A PUBLIC VEHICLE.

THE district council at Brentford prosecuted a woman recently who had moved her child from one part of Brentford to another in a cab without giving any intimation to the cabman that the child was suffering from diphtheria. The defendant's husband stated that the mother herself had had the disease and there was also evidence that she had been warned by the medical man who was attending the child as to her behaviour. Before the cab used could be traced it had been twice employed by other fares. The defendant was fined £2, with costs, which was certainly not more than her reckless and selfish conduct deserved.

THE OZONAIR MACHINE.

THE commercial applications of ozone are now numerous, owing largely to the success which has attended the designing of machines which give a steady and pure supply of the gas direct from the atmosphere. Amongst the machines which produce pure ozonised air is that known as the "ozonair," by the action of an alternating electric current of high frequency on the oxygen of the air through the medium of the silent or condenser discharge. An alternating current is therefore all that is required, but if this is not available a motor transformer may be used, by which the continuous is converted into the alternating current. This machine can be made to almost any scale and, in fact, large installations have been designed for such big operations as the freeing of the air in breweries from adventitious organisms and so ensuring a pure environment and a sound beer. The machine has also been applied to the bleaching of fabrics, oils, fats and waxes, sugar, and to the purification of water-supplies. One very important feature of the ozonair machine is that the ozonised air which it produces is entirely free from irritating nitrogen compounds. The small machines, therefore, are well adapted for therapeutic requirements, as, for example, for inhalation for antiseptic treatment, and so forth. There is attached to the machine a special air filter in cases in which a very pure air-supply is demanded, as, for example, in the operating theatre. These machines are made by Messrs. Ozonair, Limited, of 27, Chancery-lane, London, W.C., at which place they may be inspected. The cost of producing ozonised air by these machines is said to be reduced to a minimum.

◆

D. N. T. calls our attention to a method of learning the lessons to be taught by the stethoscope which is quite a useful one but by no means new. In many of the London medical schools the artifice is habitually employed.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (5th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (6th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.). Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

FRIDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (8th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (4th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 30 P.M.: Communication:—Dr. Sambon. Papers:—Dr. Bayon: The Histogenesis of Goitre.—Dr. P. Weber and Dr. Bafer: Osteolipoma of Brain. Valedictory Address: The President *(Dr. Pye-Smith).*

WEDNESDAY (5th).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M.: Specimens will be shown by Dr. Longridge, Mrs. Scharlieb, The President (Dr. H. R Spencer), and Dr. McCann. Short Communication: Dr. H. R. Andrews: Two Cases of Pregnancy in a Rudimentary Uterine Horn Papers:—Mr. H. T. Hicks: Primary Vaginal Embolic Chorion epithelioma.—Dr. Griffith and Dr. Williamson: A Case of Chorion epithelioma complicated by Hæmatometra.

THURSDAY (6th).—NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos street, Cavendish-square, W.).—8 30 P.M.: Discussion on Posterior Basal Meningitis and its Relation to Epidemic Cerebro-spinal Meningitis (to be opened by Dr. F. E. Batten).

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 P.M.: Clinical Cases.

FRIDAY (7th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 P.M.: Papers:—Dr. A. W. Addinsell: Chronic Metritis.—Dr. D. Arthur: The Diagnosis of Chest Diseases by the X Rays. (Both papers will be illustrated by lantern slides)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. J. M. H. MacLeod: Clinique. (Skin.) 5.15 P.M.: Lecture:—Dr. B. Abrahams: How to Examine the Heart (with illustrative cases).

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—12 noon: Pathological Demonstration:—Dr. Low. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Dr. Low: Insects as Carriers of Disease in Tropical Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—9 30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M: Medical Out patient (Dr. Whipham); Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Sir Dyce Duckworth: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient

Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat.

TUESDAY (4th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: *Dr. L. Williams: Clinique.* (Medical.) 5.15 p.m.: Lantern Demonstration:—Mr. J. W. T. Walker: Methods of Estimating the Renal Function.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 a.m.: Dr. Moullin: Gynæcological Operations. 2 p.m.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 p.m.: Operations. Dr. Abraham: Diseases of the Skin. 5 p.m.: Clinical Lecture:—Dr. Russell.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—10.30 a.m.: Medical Out-patient (Dr. Auld). 2.30 p.m.: Gynæcological Out-patient (Dr. Giles). Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson). 4.30 p.m.: Demonstration of Cases at the Northwood Sanatorium (Dr. J. E. Squire).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 p.m.: Dr. H. T. Hewlett: Medicine. 2.30 p.m.: Operations. 3.15 p.m.: Mr. Carless: Surgery. 4 p.m.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Skin. 4 p.m.: Special Lecture:—Mr. M. Morris: Rare Skin Affections.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 p.m.: Demonstration:—Dr. W. Wingrave: Clinical Pathology.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 p.m.: Clinical Lecture:—Dr. Ferrier: Cases in the Wards.

WEDNESDAY (5th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Mr. M. White: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. F. W. Mott: The Causes of Insanity.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 a.m.: Dr. Ball and Dr. Davies: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 p.m.: Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eye. 2.30 p.m.: Operations. 5 p.m.: Lecture:—Dr. Robinson: Gynæcological.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—2.30 p.m.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipham).

London School of Clinical Medicine *(Dreadnought Hospital,* Greenwich).—2.15 p.m.: Dr. F. Taylor: Medicine. 2.30 p.m.: Operations. 3.30 p.m.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye. 3.30 p.m.: Special Lecture:—Mr. Cargill: Optic Neuritis.

Royal Institute of Public Health (37, Russell-square, W.C.).—5 p.m.: Harben Lecture: Prof. Dr. P. Ehrlich: Experimental Researches on Specific Therapeutics.

THURSDAY (6th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. F. W. Mott: The Causes of Insanity.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—2 p.m.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 p.m.: Operations. 5 p.m.: Clinical Lecture:—Dr. Davis.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 p.m.: Medical In-patient (Dr. Chappel).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. G. Rankin: Medicine. 3.15 p.m.: Sir W. Bennett: Surgery. 4 p.m.: Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Ear and Throat. 2.30 p.m.: Special Lecture:—Dr. Rankin: Angina Pectoris.

Charing Cross Hospital.—4 p.m.: Mr. Daniel: Demonstration (Surgical). (Post-Graduate Course.)

University of Birmingham, Faculty of Medicine (Medical Lecture Theatre).—4 p.m.: Post-Graduate Lecture:—Dr. J. Miller: Opsonins.

Royal Institute of Public Health (37, Russell-square, W.C.).—5 p.m.: Special Lecture:—Prof. G. S. Woodhead: Blood Immunity.

FRIDAY (7th)—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 p.m.: Dr. H. Tilley: Clinique. (Ear.)

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 a.m.: Dr. Moullin: Gynæcological Operations. 2 p.m.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 p.m.: Operations. Dr. Abraham: Diseases of the Skin. 5 p.m.: *Clinical Lecture*:—Mr. P. Dunn.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—9.30 a.m.: *Clinique*:—Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. Leslie).

London School of Clinical Medicine (Dreadnought Hospital, Greenwich).—2.15 p.m.: Dr. R. Bradford: Medicine. 2.30 p.m.: Operations. 3.15 p.m.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Skin.

National Hospital for the Paralysed and Epileptic (Queen-square, Bloomsbury, W.C.).—3.30 p.m.: *Clinical Lecture*:—Mr. Armour: Surgical Treatment of Infantile Paralysis.

Central London Throat and Ear Hospital (Gray's Inn-road, W.C.).—3.45 p.m.: Demonstration: Dr. W. Wingrave: Clinical Pathology.

Royal Institute of Public Health (37, Russell square, W.C.).—5 p.m.: Harben Lecture: Prof. Dr. P. Ehrlich: Experimental Researches on Specific Therapeutics.

SATURDAY (8th).—London School of Clinical Medicine (Dreadnought Hospital, Greenwich.)—2.30 p.m.: *Operations.* Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye.

Post-Graduate College (West London Hospital, Hammersmith-road, W.).—10 a.m.: Dr. Ball and Dr. Davis: Diseases of the Throat, Nose, and Ear. 2 p.m.: Medical and Surgical Clinics. X Rays. Dr. K. Scott: Diseases of the Eye. 2.30 p.m.: Operations.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.				To the Colonies and Abroad.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

During the week marked copies of the following newspapers have been received:—*Belfast News Letter, Daily Express, Surrey Comet, Islington News, Northern Whig, Daily News, Morning Post, Daily Telegraph, Daily Chronicle, The Star, Darlington Echo, Scientific American, Literary Digest (New York), Brecon County Times, Liverpool Daily Post, Pharmaceutical Journal, Yorkshire Post, Standard, Morning Post, Morning Leader, &c.*

Communications, Letters, &c., have been received from—

A.—Dr. J. Adam, West Malling; Messrs. Aked and Aked, Lond.; A. W. L.; A. G. M.

B.—Dr. W. Blair Bell, Liverpool; *The Bakers' Magazine*, Lond., Proprietor of; Messrs. Burroughs, Wellcome, and Co., Lond.; Dr. F. C. Beechtel, Denver, U.S.A.; Mr. E. Baker, Birmingham; Mr. F. E. Bennett, Margate; Messrs. S. K. Broadbent and Co., Douglas, Isle of Man; Messrs. Barclay, Perkins, and Co., Lond.; Mr. E. W. Blasius, Lond.; Mr. Arthur E. Barker, Lond.; Mr. Albert Benthall, Lond.; Mr. Adolph Bronner, Bradford; Mr. F. D. Bennett, Lond.; Bread and Food Reform League, Lond., Hon. Secretary of; Bolton Guild of Help, General Secretary of.

C.—Mr. R. P. Culley, Cardiff; Colonial Nursing Association, Lond., Secretary of; Right Hon. Winston Churchill, P.C., M.P., Lond.; Messrs. Cary, Porter, Lond.; Dr. G. H. Colt, Lond.; Dr. H. Campbell, Lond.; Dr. W. T. Connell, Kingston, Canada; Lieutenant T. J. Crocker, R.N., Woolwich; Messrs. J. and A. Churchill, Lond.; Cheltenham General Hospital, Secretary of; Messrs. Crossley and Co., Lond.; Messrs. Cassell and Co., Lond.; Mr. F. W. Clarke, Chorlton-cum-Hardy; Messrs. Curtis and Henson, Lond.; Messrs. J. W. Cooke and Co., Lond.; Mr. T. Colvin, Glasgow.

D.—Mr. W. Dandie, Hereford; Dumfries and Galloway Royal Infirmary, Secretary of; Dr. Gustav Dintenfass, Vienna; Messrs. S. Deacon and Co., Lond.; Dr. A. D. Ducat, Chiswick.

E.—Major P. Evans, R.A.M.C., Cairo; East Suffolk and Ipswich Hospital, Secretary of.

F.—Dr. Francis Fremantle, Lond.; Messrs. Ferris and Co., Bristol; Mrs. Forster, Christon Bank; Messrs. Fastersen and Co., Basle; Messrs. Foster, Brown, and Co., Montreal; Forward Publicity Co., Birmingham; Messrs. Flint, Pitt, and Durbridge, Lond.; Dr. A. Fullerton, Belfast.

A Lecture

ON

VAGAL AND VASO-VAGAL ATTACKS.

Delivered at the National Hospital for the Paralysed and Epileptic on May 21st, 1907,

BY SIR WILLIAM R. GOWERS, M.D. LOND., F.R.S.,

CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, ETC.

GENTLEMEN,—The term "vagal attacks" is, no doubt, unfamiliar to you. It seems a useful designation for prolonged seizures, the symptoms of which consist chiefly in disturbance of some of the functions of the pneumogastric, for the most part sensory and subjective. Similar attacks have been described by Pierre Bonnier as "syndromes médullaires."[1] With the vagal symptoms there is often combined a slight mental change and also disturbance of the vaso-motor centre causing constriction of the vessels and coldness, especially of the extremities. Associated with the latter may be some sensory impairment and sometimes also a form of slight tetanoid spasm. These features vary much in relative proportion, so as often to obscure the relative resemblance. When the vaso-motor spasm preponderates the case may seem to differ from the type more than it really does. Such cases may be termed "vaso-vagal." The attacks are never really brief; they seldom last less than ten minutes and more often continue for half an hour or more. There is a sudden onset of slight symptoms, rapidly increasing, and the ending is gradual. The seizures recur at varying intervals, often for months or years.

Women suffer far more frequently from these attacks, but they are also met with in men. This, and the fact that the pneumogastric and vaso-motor systems are readily influenced by emotion, has probably led to the submergence of these attacks beneath the vague conception of hysteria, a conception which conceals whatever it covers. *You must rescue* from it whatever you wish to study. You can put it back again afterwards if you like. Before describing to you some of the cases I have met with, the special symptoms may be briefly considered.

The vagal symptoms are chiefly sensations referred to the stomach, the respiratory system, and the heart. At least, we may probably ascribe to the gastric nerves a sensation referred to the epigastrium, described as a sense of oppression or of fulness, but often indescribable. It begins suddenly, irrespective of the state of the stomach or of its functions, and often seems to ascend to the chest, very seldom to the throat or head, as does the aura of epilepsy. There is seldom nausea and never vomiting. Even more common, especially as an early symptom, is a sense of respiratory distress, of difficulty in breathing. It is sometimes so intense as to amount to orthopnœa and to compel the sufferer, if lying, to sit upright, although there is no corresponding sign of impairment of breathing. With this may be combined cardiac symptoms, discomfort, acute pain in some cases, often a sensation of sudden stoppage of the heart, followed by rapid action. With the dyspnœa, or the cardiac sensation, or both, is often associated a sense of impending death, so intense that no recollection of its falsity in preceding attacks prevent the conviction of its present reality. It naturally causes alarm, but apart from this there is sometimes a sense of intense fear and dread, which is recognised to have no adequate cause.

Although there is no impairment of consciousness in typical cases, a peculiar slight mental state is common, and may even be the first symptom. It is generally described as a difficulty or slowness of mental operations, a difficulty in thinking or in concentrating attention. Trifling as it may seem, it always begins suddenly and strikes the patient as a state quite unlike the normal condition. Sometimes it involves a slowness in speaking but this seems partly due to the sense of dyspnœa. Perhaps allied to this, is a sudden sense of physical fatigue, which also is often an initial symptom.

The vaso-motor spasm sometimes attains a high degree. To it the symmetrical coldness is certainly due, for the pulse becomes small at the same time. When general, there is pallor of the face. Shivering is common and may amount to a definite rigor, but this occurs when the coldness is beginning to lessen. With the coldness of the extremities tingling and numbness in them are often described and sometimes there is the tetanoid spasm we shall consider later.

CASE 1.—A fairly typical case was a single woman, aged 28 years, whose cousin was epileptic. She had suffered for nine months from attacks that were heralded by occipital headache on waking in the morning. Some time in the forenoon she suddenly found that she could not fix her attention on any subject. After this had lasted an hour or so a sense of sleepiness came on; then suddenly she felt wide awake with an intense sense of fear, extreme coldness of the hands, feet, and legs, and inability to move. Presently a peculiar, indescribable sensation was felt at the epigastrium and back, sometimes with slight nausea. After a few minutes of this, violent beating of the heart set in, accompanied almost at once by an intense sense of suffocation. If lying she had to sit up to breathe, though there was no evidence of dyspnœa. Then the attack subsided, as a flush developed, attended by slight perspiration and a flow of tears (without any sense of emotion). The flush was accompanied by a sense of warmth, beginning in the head and passing to the arms, but with this there was always a slight distinct rigor. The teeth would chatter and the hands would shake. It was greater the more severe the attack. This soon ceased and she was well. During the attack there was a curious sense of unreality in all she saw and afterwards objects were blurred and indistinct. Some more severe attacks began with tingling in the hands and arms, face, and trunk; the epigastric sensation developed to definite nausea: the general coldness was extreme, "as if made of stone," and the violent action of the heart was preceded by a feeling that it had stopped and that she was dying.

CASE 2.—The case I have next to mention is remarkable in its features, although the true vagal *symptoms are subordinate* to the disturbance of the vaso-motor system. It is notable also from the fact that the subject of such pronounced attacks was a man, an officer in the army, aged 30 years. Two of his sisters were insane. The seizures were not frequent; they had occurred about once in six months for 12 years, ever since he was 18 years old. Their character was always the same, such as one of which I saw the later part. Earlier in the day he had been in specially good spirits, an antecedent often noted. Quite suddenly, a dreamy mental state came on, a reminiscent state, the well-known feeling that whatever was happening had happened before. It was not momentary as in epilepsy, but went on. With it, or just after its commencement, his hands and feet became cold; his own belief was that the mental state was first noticed. With the coldness, his face became increasingly pale and physical prostration set in, speedily reaching such a degree that he was scarcely able to move. If he tried to sit up he fell back at once. His extremities became icily cold, even to an observer. So great was the prostration that he could only utter one or two words at a time with an effort (apparently from the respiratory difficulty in phonation). His pulse became smaller and smaller, until it was hardly perceptible. There was not a moment's loss of consciousness throughout. His own sensation was that he was dying, gradually passing out of physical existence. This state lasted about half an hour and then he gradually became aware simultaneously that his mental state was improving and that his feet were a little less cold. The amelioration went on, but two or three minutes after its commencement a distinct rigor set in, with shivering and chattering of the teeth. It lasted about two minutes and always occurred at this stage, coincident with gradually increasing warmth. A few minutes after the rigor an urgent need for micturition was felt and went on during the rest of the day, a large quantity of limpid urine being passed. No sense of undue warmth or rise of temperature followed the attack; indeed, he continued pale for the rest of the day. Treatment arrested the attacks almost at once (as will be presently mentioned) and 17 years afterwards I ascertained that his recovery had been enduring. Although he had been in India and had suffered from malaria before the age of 30 years, this could not have been the cause of the rigor, because it was a feature of the attacks from the beginning, before he entered the army.

It is instructive to compare these two cases. Although isolated vagal symptoms were not conspicuous in the second, both present certain features in common—an initial slight mental change, the sense of impending death, the coldness, and the shivering as this was beginning to lessen. While it may be thought possible that in some vagal cases I shall mention the feeling of coldness may have been a sensation only, independent of the vaso-motor system, in this case it cannot be thus explained. The vaso-motor derangement was obtrusive and we shall see that in other instances it was equally clear. Whether the physical enfeeblement was due to the participation of the brain in the vascular spasm we cannot say; the general character of the case suggests it. The difficulty in speaking, if of respiratory origin, is another point in common with other cases. When these have been described and considered I think it will not be doubted that this case is closely allied to the others.

---

[1] Pierre Bonnier: Le Vertige.

CASE 3.—Let me mention, as briefly as I can, some other examples of vagal attacks. The sense of impending death, so frequent in severe forms, seems connected with disturbance sometimes of the cardiac, sometimes of the respiratory functions of the vagus, or with both. In its cardiac associations it naturally arouses a suspicion of angina pectoris. It did so in a man of 39 years, who had suffered since the age of 33 from occasional momentary giddiness, even when sitting still, suggestive of the slightest form of minor epilepsy. Six months before he was seen these ceased and were replaced by peculiar and more prolonged attacks. First he felt a sensation of slight pricking in his hands and feet, combined with a cramp-like feeling; they became colder and colder, and his face grew pale. After about a minute he felt at the heart a peculiar sensation, which he could not describe, accompanied by intense fear and a feeling that he could not get his breath. So intense was the sense of distress that he "hardly knew where he was," but he was certain that he never lost consciousness. After about five minutes in all the attack gradually passed away. The fact that no pain attended the sense of thoracic distress is a sufficient distinction from true angina pectoris, for which it had been mistaken. Sensations are often called pain which careful questioning shows to be different, and this always implies a different significance.

CASE 4.—The two cases that follow are of similar character. They exemplify, moreover, a relation of these attacks to preceding migraine which is not uncommon. A married woman, aged 47 years, with gouty heredity, had suffered from characteristic migraine as long as she could remember. For two years she had been liable to peculiar attacks at intervals of a few days or longer, even as much as two months. A distressing sensation at the epigastrium, described as "fulness" or "oppression," came on quite suddenly and ascended to the middle of the chest; it was attended by an extreme sense of prostration, but there was no pain or nausea. Her heart became excited and her pulse, usually 90, rose to 120; the face became pale, and the extremities cold and clammy; the were hands so insensitive that she could hardly feel what she touched. There was no impairment of consciousness and after ten minutes the attack gradually passed off.

CASE 5.—In another woman, aged 52 years, also subject for long to migrainoid neuralgia, attacks occurred which began with a sense of dyspnœa followed by coldness, especially of the feet, and a sense of "numbness" which passed up the legs and body and involved the arms. The hands became dusky and fixed, with the fingers flexed. Sometimes she was unable to speak for a few minutes. The attack lasted about half an hour and ended gradually.

Coldness in the extremities is often, as I have said, attended by tingling in them and some defective sensation and also by a tendency to tonic spasm. The last is like that of tetany except that the posture of the fingers is different from that of typical tetany, the fingers being flexed at all joints, a position sometimes assumed in the ordinary form. This spastic feature is conspicuous in some vagal attacks apart from vaso-motor spasm.

CASE 6.—One case in which it was marked had given rise to much doubt regarding its possible epileptic nature. A lady, aged 25 years, had married at 19 years of age and had borne five children during the next four years. The attacks began after phlebitis subsequent to her last confinement, at the age of 23 years, and had continued since, sometimes as frequently as two or three each week. Each began by a sense of difficulty in breathing and coldness in the hands, with some tendency to contraction in them. In a few minutes pain was felt at the heart and the sense of dyspnœa increased and there was a slight flush on the face. From the onset objects seemed far away, and sounds faint and distant; she was also conscious of an inability to think and a difficulty in finding words; "it was a bother to speak." In one which I saw she uttered only two or three words at a time, as if she could not get enough breath for speaking, and her aspect was distressed. In this there was no evident contraction of the hands but she was constantly trying to bend back the fingers of one or the other hand, as if from a feeling of cramp in them. Severe attacks began with deep breathing and sometimes the sense of dyspnœa compelled her to sit up, with deep flushing of the face but no duskiness. The hands became very cold, with strong flexion of the fingers. The duration was from five minutes to a quarter of an hour. She never lost consciousness, even for a moment.

The symptoms of this case are typical, and the conscious difficulty in thinking, as an early symptom, is of interest in connexion with the similar symptom in Case 1. The symptoms were peculiar in the dominant tetanoid contracture, which was out of proportion to the vaso-motor spasm. I learned later that the attacks gradually lessened until she became almost free but were subsequently renewed by an alarming carriage accident.

CASE 7.—An instructive connexion between *ordinary* paroxysmal tetany and the vagal form was presented by a married woman, aged 31 years. A year before she had a long attack of gastric catarrh, with vomiting, in the course of which she had a severe attack of tetany, lasting six days, accompanied by elevation of temperature to 102° and 103° F. and a feeble pulse. The fingers were in flexion at all joints, as is sometimes the case in the ordinary form. The gastric symptoms passed away but she had another attack of tetany a month after, much shorter, a third three months later, and a fourth after another four months. The latter two attacks lasted only a few hours. Each began with an unpleasant sensation at the epigastrium, followed in a few minutes by contraction on both sides of the face, with the mouth open; the tonic spasm passed to the arms and hands and down the legs to the feet, which were fixed in extension, the fingers being flexed. As this developed, the epigastric sensation passed to the thorax generally and became intensely distressing, giving the impression that she was about to die. Brief remissions occurred during the attack, which, after a few hours, passed off in the opposite order to that of the onset. For some days before an attack she experienced, for a few minutes at a time, slight premonitory symptoms. A brief sensation at the epigastrium, with some nausea, seemed to her to pass into the limbs and to cause slight rigidity in them. These symptoms occurred without relation to food or external circumstances. In the severe attacks the passage of the sensation to the thorax was not attended by dyspnœa and the sense of impending death was not apparently the result of spasm but resembled that experienced in severe vagal attacks.

RELATIONS TO EPILEPSY.

The cases I have described present no definite relation to epilepsy. The symptoms were deliberate, slow in evolution, unlike the sudden flash-like character of the elements of the epileptic attack. But we meet with cases that seem to connect the two classes and to establish the position of even the vagal attacks in the borderland of epilepsy. The features of such cases must be individually studied, for they do not admit, at present, of clear generalisation.

CASE 8.—One patient, when a girl of 13 years, began to have attacks at intervals of a day or a week. Each began with a sudden feeling of intense fatigue and giddiness—a sensation that objects were moving swiftly to the left and changing in colour to purple and red. The feeling made her inclined to fall, but in a few seconds it was over. Note that the colours, as well as the initial sense of fatigue, distinguish the attacks from simple vertigo. She had also occasional severe headaches, without sensory prodroma. These went on until the age of 16 years. She was first seen then, but not again until she was 28 years old. She had married in the meantime and the attacks, which had ceased after she was seen, subsequently recurred in a somewhat altered form, which is peculiarly instructive. Each began as before by a sudden sense of fatigue, which was not followed by the sense of movement and of colours, but by a second's loss of consciousness; sometimes this was only loss of sight, a moment's sudden absolute blackness. These made more emphatic the epileptic nature of the attacks. After another year their character had again changed. The sudden sense of fatigue was followed by yawning, several times repeated, and then loss of consciousness for a second or two, after which she was well. But she did not always thus lose consciousness; sometimes the yawning was followed by a sense of want of breath amounting to distressing suffocation and also by a sensation of peculiar distress below the heart. The effect of these was to make her feel that she must keep perfectly still or she would faint. If she kept quiet the sense of suffocation continued for an hour, or even for two hours, before subsiding, but at any time during its course it might be suddenly ended by a moment's loss of consciousness. The attacks came on when awake or asleep, but if sleeping they were always of the early brief form. She waked up with the sense of fatigue, at once lost consciousness for a moment, and was better. By day they often occurred when sitting still, but sometimes they were excited by rising suddenly from the sitting posture. The brief attacks were clearly epileptic. In those of long duration a vagal symptom was interposed, the respiratory and cardiac distress, which endured for long, but was at any time terminated by a moment's loss of consciousness; this seemed at once to relieve the state of brain tension that caused the distress. We can perceive the mysterious relation, although we cannot explain it. The important fact for our present subject is the interposition of prolonged vagal symptoms in the course of an epileptic attack, as if symptoms, usually momentary, as the aura of epilepsy, became protracted, extended as it were, into a vagal attack.

CASE 9.—The following case is similar but differs in that the loss of consciousness did not end the attack but was interposed between the vagal and the vasal symptoms. A married woman, aged 35 years, without neurotic heredity, had suffered for two years. The attacks occurred at intervals of ten days to two months, always without excitant, often when sitting still. A sudden intense sense of suffocation, with a feeling of tightness in the head, was followed, after a minute or so, by a moment's complete loss of consciousness. On its return she felt cold, first and most in the extremities. The coldness was so intense that it made her shiver. After about ten minutes she burst into perspiration and simultaneously her heart began to beat violently and the symptoms slowly subsided. Most attacks were similar, but she occasionally had one that was much slighter and consisted only in a brief sense of suffocation.

CASE 10.—With the last case it is instructive to compare another. A woman, aged 28 years, had suffered from attacks for three years, at first at intervals of two or three months, then more often, until of late she had two a week. A sudden sense of great fatigue, succeeded by coldness, was followed in a minute or two by dimness of sight and then loss of consciousness, so sudden as to cause a fall, always backwards. There was no convulsion. After five minutes consciousness began gradually to return. First she could hear loud sounds, then voices, at first indistinctly. Then objects could be seen as in a fog, afterwards clearly. The process of slow recovery occupied about half an hour. But the most significant fact is that she had also slighter attacks with no loss of consciousness, lasting half an hour and closely resembling those of "vagal" character. There was a sudden sense of dyspnœa, respiratory distress, and of faintness, accompanied by a sensation of coldness, especially in the face, on which "icy air seemed to be blowing." Sight became rather dim, and when it slowly returned objects seemed unreal, "as if in a picture." Thus the patient seemed to suffer from epileptic attacks and also from those of the class now considered, but the two were not entirely disconnected in their features.

The case I just now described, in which prolonged respiratory distress was instantly terminated by a moment's loss of consciousness, is suggestive for another reason. We must regard it as epilepsy, but it was a minor attack extended, protracted, drawn out as it were, so that the initial sensory stage, instead of being momentary, often continued for a long time. It might even subside without the usual loss of consciousness. It is foreign to our thoughts to conceive the idiopathic epileptic attack as capable of extension, and yet we know that the aura varies in length and we have no reason to believe that it cannot be prolonged. In local attacks from organic disease, we meet with some that are prolonged, either as sensory discharge or as clonic spasm. The slighter attacks may sometimes endure for a quarter of an hour or longer. In these the tendency for consciousness to suffer is not great. In vagal attacks the symptoms, respiratory and cardiac, which are gone as soon as felt in a true epileptic seizure, seem to be most distressing when prolonged. This can readily be conceived. Full perception is not momentary and with time there seems to be what physiologists term a "summation of sensation," even of that which is purely subjective.

These facts suggest that if we can conceive a minor epileptic attack that is extended, its elements protracted, with no tendency to be terminated by loss of consciousness, its features would be so different that its nature would not be suspected. Velocity altogether alters the effect of momentum. A bullet fired from a rifle makes a round hole in a pane of glass, which it would smash if thrown against it. Velocity is an essential element of ordinary epilepsy, but this does not preclude the possibility of deliberation in attacks not far removed from epilepsy.

I will conclude with the description of an attack of slow deliberate character which has some features in common with those that merit the term "vagal," and yet differs from them in its more pronounced subjective emotional distress. It is easily regarded as hysterical, but even then its features deserve consideration.

CASE 11.—The subject was a married woman, aged 35 years. Her nervous system was unstable and excitable in a high degree, such as to suggest any kind of hysterical disturbance. Yet throughout her life she never had any ordinary hysterical attack. She was apprehensive of evil in a degree that made her life distressing to herself and perplexing to others. In childhood she had some attacks that seemed to be definite *petit mal*, with loss of consciousness so sudden as to cause her to fall in each. They ceased after childhood, but there were subsequently occasional, but rare, threatenings. When 33 years old she had another definite minor seizure; there was a sudden sensation of intense coldness at the vertex; she instantly fell unconscious, but at once recovered. The special attack with which we are concerned occurred two years later, after some mental anxiety. She was feeling well, and was occupied as usual, when she had a sudden strange sensation that her mind was acting slowly; an effort was needed to understand what was said to her. This difficulty increased and extended, so that in a quarter of an hour all about her seemed strange and unfamiliar, and an observant nurse who was present averred that for a short time she clearly did not know where she was. She walked into the garden but became worse rather than better. Then, quite suddenly, some intense physical sensation occurred which gave her the impression that she was dying. She begged that her husband should be called in order that she might say farewell to him, although he was then far away. This seemed to mark the turning point, for in a few minutes the physical distress lessened and she began to improve, but for an hour more, when spoken to, she seemed to hear the words at once, but could only grasp their meaning slowly and with considerable difficulty. At the end of one and a half hours from the onset she was quite well again. Throughout, the nurse closely observed her and could see no pallor, while her pulse was unchanged in frequency or strength. It was afterwards ascertained that, besides the indications of minor epilepsy already mentioned, she had experienced, many times during her life, and two or three times during the previous year, a sudden sense of strangeness. For a moment she did not know where she was. Once she seized her husband's arm and exclaimed, "Oh, where am I?" but almost as soon as the words were uttered the feeling was gone. This is a familiar form of minor epilepsy. A significant fact is that she recognised the identity of this momentary sensation with that which developed gradually in the prolonged attack. This, as I said, may easily be regarded as hysterical, but its features suggest that its nature was rather that of a prolonged slow cerebral process which, if condensed into a few seconds, might have involved loss of consciousness and have been a characteristic attack of minor epilepsy. It was attended by intense distress to the patient and left her with constant dread of a recurrence, but this had no effect in producing one. If its features are compared with those previously described it will be found to present two characters in common with them. It began with the strange sense of a difficulty in mental processes, which continued, and is, as we have seen, common in vagal attacks. It also presented the sensation of impending death, which was probably produced in some way through the vagal functions. Perhaps the term "psycho-vagal" would be the most accurate designation for such an attack.

TREATMENT.

In the treatment of sufferers from such attacks it is, of course, essential to discover any defect in the general health and anything in the conditions of life that involves strain on the nervous system and to put these right as far as may be possible. Conspicuous anæmia is not often to be found, but constipation is common and harmful, especially with its attendant indigestion. It is very seldom that any exciting cause can be traced for the attacks that can be avoided but it is important that the patient should be free from all causes of over-fatigue. When an epileptic element can be traced much good is usually obtained from bromide in moderate doses, combined with belladonna or digitalis. Nitrite of amyl deserves a trial at the onset of attacks and a slight inhalation of chloroform if the opportunity presents itself. But in all cases in which there is vaso-motor spasm the regular administration of nitro-glycerine is by far the most useful agent. Taken regularly, although no effect may be perceived from it at the time, it seems to exert a permanent, steadying effect on the vaso-motor centre, and strychnine may be combined with it with advantage. A striking instance of its effect was presented by the patient with such severe coldness and prostration (Case 2). In his own words it seemed to act "like a charm." He had no other attack and after taking it regularly for many months it seemed to leave him free from any tendency to those which had gone on for 12 years. Nerve tonics, such as phosphorus, quinine, and valerianate of zinc, are sometimes useful.

ABSTRACT OF

An Address

ON

THE NATURE OF INFECTIVITY IN RELATION TO TUMOUR GROWTH.

Delivered in the Section of Pathology and Bacteriology at the First Australian Dental Congress, Sydney, in February, 1907,

BY D. A. WELSH, M.A., B.Sc., M.D. EDIN.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF SYDNEY AND CHAIRMAN OF THE SECTION.

The infective nature of tumour growth.—When bacterial cells gain access to the animal body one of two things may happen—either they are antagonised and are killed off by the defensive mechanisms of the tissues or the resisting powers of the tissues are overcome by the numbers and virulence of the bacteria. In the former case the bacteria disappear from the body and no infection occurs; in the latter case the bacteria thrive and multiply in the tissues and the animal is said to become infected. The essence of the process of infection, therefore, is that the bacterial cells concerned have entered the tissues and have begun to multiply there. A disease which depends upon the proliferation and multiplication of alien cells within the animal body is termed an infective disease, and if, in addition, the disease is capable of being transmitted from one animal to another (by transference of the infective cells) it is spoken of as infectious. A disease may thus be infective—that is, due to invasion and proliferation of hostile cells—without being infectious—that is, transmissible to other animals. To this category, as we shall presently see, cancer may be said to belong.

For our present purpose the ultimate unit in a cancerous growth may be taken to be the individual cancer cell, and although each cancer cell is the direct descendent of some pre-existing cell within the organism in which it grows, nevertheless the cells of a cancer become at a very early stage differentiated and sharply marked off from all the other cells of the organism. Whereas the cells of the healthy animal body are all working for the common good, the growth and activities of each tissue and cell being so conditioned and regulated as best to attain this end, the cancer cell appears as a seceder from this commonwealth. The growth of cancer proceeds independently of, and, indeed, at variance with, the requirements of the organism and, further, the regulated and orderly growth of the parent tissue is exchanged for the unregulated and disorderly growth of the tumour. The absolute nature and extreme degree of this two-fold independence—independence of the needs of the organism and independence of the laws of tissue growth—are the basis of that hostility so characteristic of cancerous tumours. Although bearing a most intimate developmental relationship to the cells of the parent organism or tissue the cancer cell is essentially hostile, just as hostile, for example, as bacterial cells may be when they effect a lodgment in the tissues.

There is yet a third manifestation of independence exhibited by cancer cells, inasmuch as they grow independently of one another. Particularly is this the case at the advancing margin of a cancerous growth, where any one cell appears to be equivalent to any other, and all are mutually independent. So far as we know any one cell detached from the advancing margin is capable of starting a secondary nodule in another part of the body, and it is as untrammelled in its growth as, in similar circumstances, a pathogenic bacterium would be. There is thus a close parallelism and a suggestive analogy between the general characters of cancer cells and the general characters of bacterial cells. For whatever the ultimate nature of cancer may prove to be, this at least is certain, that it constitutes an invasion of the organism by a brood of independent and hostile cells, and that once these cells have made their appearance within the organism they may undergo a practically indefinite and unlimited multiplication and proliferation. But these are precisely the conditions that go to make up the process of infection, and so we reach the general conclusion that, in a very definite and intelligible sense, cancer is an infective disease—as certainly infective as any disease due to an invasion of the organism by other parasitic cells, whether of bacterial or of animal origin (as in malaria and in trypanosomiasis). This is not a new theory; it is merely a re-statement of accepted facts, marshalled, I trust, without distortion. So far as I can conceive the nature of cancer growth, this attribute of infectivity is fundamental and the recognition of it is independent of any hypothesis that may be formed regarding the origin of cancer. To my mind, also, a due appreciation of the infective nature of cancer tends, not to confuse, but to coördinate certain phenomena of tumour growth, such as relative malignancy, which otherwise are hard to apprehend.

One hypothesis regarding the origin of cancer, widely known as the "parasitic theory of cancer," is suggested by the analogy between cancer cells and other bacterial or animal parasites capable of producing disease. This hypothesis is based on the observation that cancer cells not infrequently contain within their substance peculiar bodies, "cell-inclusions," which bear a more or less close resemblance to certain low forms of organised life. It is assumed that these appearances represent stages in the life-history of some parasitic micro-organism which has invaded the cancer cell, and it is suggested that the malignant proliferation of cancer cells is induced by some stimulus supplied through the agency of the minute parasites within them. It may be that the cause of cancer will ultimately prove to be some parasitic microbe infesting its cells. As yet, however, this is far from being an established fact, and the hypothesis has the further demerit of being hard to reconcile with some of the known facts of tumour growth. But *our point* is this, that although the existence of a specific cancer parasite is at the best doubtful, the existence of the parasite, cancer, is beyond a doubt. It is not in the commonly accepted sense, therefore, that I would advocate a "parasite theory of cancer"; what I would emphasise is the fact that the cancer cell is in itself a parasite and is endowed with that formidable attribute of the more highly pathogenic parasites—the attribute of infectivity.

The non-infectious nature of tumour growth.—Two of the most serious obstacles to the scientific study of tumour growth have been the impossibility of originating a new growth by any artificial means and the difficulty of transmitting a new growth from one animal to another. The former has not even yet been overcome, the latter only within recent years. Up to the year 1902 (I am quoting from a previous address of mine on this subject) only a few isolated instances of successful transplantation of tumours from one animal to another had been recorded. The first to achieve systematic success was Professor Jensen, of Copenhagen, whose results were not made generally known until 1903. In the same year Borrel of Paris published another series, and in 1904 there appeared the first scientific report of the Imperial Cancer Research Fund, in which further examples were noted. All these successful results were obtained by transplanting tumours of mice to other mice. In the case of no other animal, with the single exception of the rat (which is of the same genus as the mouse), has the transplantation of new growths been successful.

Jensen's original tumour growing in a white mouse was regarded by him as an epithelioma. Introduced into other mice it yielded from 30 to 60 per cent. of successful inoculations and it has proved to be one of the most readily transmissible of all new growths hitherto tested. It is still growing, like a pure culture of bacteria, in various laboratories on the continent of Europe, in England, and in America, the medium on which it thrives being successive generations of mice. In its duration of life (five years) it has nearly doubled the natural term of life of a mouse and in bulk it has exceeded that of many thousands of mice. This great power and persistence of growth are equalled only by the natural propagation of successive generations of mice and indicates a source of potential vitality in the cells of the cancer comparable only to that which secures the continuance of the race.

Having regard to these considerations and bearing in mind also that cancers have never been transferred from man to other animals, nor, indeed, from any animal to another of different species, we must admit that the transmissibility of cancer is exceedingly restricted—that, as a matter of fact, it is limited to the occasional experimental infection of one small rodent from another by direct inoculation with living cancer cells. Nevertheless, evidence of endemic outbreaks of cancerous, or cancer-like, tumours among various animals has from time to time been advanced. Hanau and Loeb in rats, Borrel and Michaelis in mice, Cooper and Loeb in cattle, Pick and Bonnet in trout, have each reported instances of the appearance of cancer affecting so large a proportion of animals in one place as to suggest some common source of infection. More recently Gaylord has submitted certain facts which suggest that infected cages may be the source of spontaneous cancer developing among small caged animals, including rats and mice. And, in regard to the liability of the human subject, the existence of "cancer houses" and "cancer districts" in which there occurs a succession or an undue proportion of deaths from cancer has repeatedly been alleged. I would not criticise adversely statements advanced by able and competent observers, which I have no means of testing for myself, further than to point out to you that many cancer-like tumours are admittedly infectious, that they are often hard to distinguish from true cancers, and that much of the evidence above quoted is open to the objection that the tumours either were not examined at all, or were not convincingly differentiated from infectious non-cancerous growths.

In approaching the study of a subject so vast, so elusive, and so occult as that of the nature of cancer we must be particularly careful to keep our minds free from bias and to avoid precipitate conclusions We must be prepared to admit all evidence on its merits without discounting its significance by reference to our preconceived notions. We must, for example, hold ourselves intellectually in readiness to accept the possibility that cancer may be due to the agency of some parasite or that cancer may be naturally infectious. With this proviso, however, and with the evidence before us, I am bound to confess that, in respect of human forms in particular, I fail to discern any cogent reason for regarding cancer as an infectious disease.

The nature of relative malignancy.—It is customary to divide new growths into two groups—the simple, benign, or innocent on the one hand, and the malignant or cancerous on the other. The more opportunities I have for the study of tumour growth the more am I convinced that all new growths are essentially malignant, though all are not equally malignant. The differences recognisable in their mode of growth are differences in degree and not in kind, and all degrees are possible. The most benign of tumours possesses, though in lesser measure or in modified form, all the fundamental attributes and capacities with which the most malignant new growth is endowed. From a clinical standpoint it is of the utmost importance to be able to say whether a growth is of a low order (benign) or of a high order (malignant) of malignancy; but from a scientific point of view it is no less important to recognise that the distinction does not mark any fundamental difference between the two classes of new growth. Malignancy, as I understand the term, is only another expression for infectivity, an attribute common to all forms of new growth, but developed to a variable degree in different forms. Clinically "malignant" growths are made up of cells whose infective capacity is high; clinically "benign" growths are composed of cells of low infective capacity.

We can best understand how the malignancy of a new growth is determined by its infectivity if we have recourse once more to the analogy furnished by bacteriology. Among infective diseases marked differences exist as regards the distribution of the causal bacteria within the body and as regards their capacity for infection. In some infections the multiplication of the bacteria is localised, and the microbes are restricted to the original site of infection, as in the case of a small local abscess. In other conditions the bacteria are not so restricted, but may extend widely into the adjacent tissues, as in cases of spreading inflammation or suppuration, though they may not appear in the blood or in remote tissues until just before death. In yet other circumstances whether the local proliferation be restricted or extended, the bacteria may show a special tendency to enter the lymphatic or the blood channels and thus to give rise to widely disseminated lesions, as in tuberculosis or in pyæmia. Every one of these types of lesion, apparently so diverse, may be produced by one and the same organism, according as its virulence—in other words, its capacity for infection—is modified.

Now the phenomena of tumour growth present may close analogies to these phenomena of bacterial infection. Some new growths remain localised and their component cells show little or no tendency to infiltrate (infect) adjacent tissues, nor do the growths tend to recur after removal. In others the cells are prone to local infiltration (infection) and the growths to inveterate local recurrence, but they may not give rise to secondary nodules until late in the course of the disease. In yet others the tumour cells, in addition to local infiltration, may have developed a special tendency either to extensive lymphatic infiltration or to invasion of blood-vessels, in the former case originating a widespread lymphatic infection, as in tuberculosis, and in the latter case causing the dissemination of secondary embolic growths analogous to pyæmia. In fact, if for the word "bacterium" we substitute "tumour cell" and for "inflammation or suppuration" we speak of "tumour growth" we obtain a corresponding series of statements which are in accordance with the main facts of tumour growth, and we are in a better position to understand that, just as in the case of bacteria, so also in the case of tumour cells, it is their capacity for infection that conditions the extent and manner of their dissemination within the body. What we denote "virulence" in respect of bacteria becomes "malignancy" in respect of tumour cells, and each expression may, for our present purpose, be regarded as equivalent to "infectivity." The effective malignancy of a new growth, however, may be modified by the physical conditions of its structure. Some of the more malignant forms may be largely restricted to local manifestations of malignancy because of the structural cohesion among the individual cells and the physical difficulty of their becoming detached from the parent mass.

The local and the general reaction.—In many bacterial infections the proliferation of the bacteria induces a local reaction and proliferation of tissue cells which may thus come to form a localised swelling or "tumour." But it is not in this sense that the term tumour is employed in reference to cancers and other new growths. In the so-called "tumours" of bacterial origin the bulk of the bacteria is practically negligible and the mass is made up of proliferated tissue cells and other inflammatory products; whereas in the tumours proper, including cancer and other forms of new growth, the mass may consist almost entirely of the infective tumour cells, although in many cancers the products of tissue reaction may come to bulk more largely than the cancer cells themselves. Other differences between cancerous and bacterial infections may be correlated with differences in the nature of the infecting agent. Thus cancer cells, unlike bacterial cells, are the direct descendants of cells within the organism. Probably on account of this intimate genetic relationship they induce a less marked reaction on the part of the organism than do the alien bacterial cells. For example, while cancer cells may induce a local inflammatory reaction greater than that associated with some bacteria, they do not appear to stimulate that general reaction on the part of the organism which is so prominent and characteristic a feature of most bacterial infections that recovery is the rule and death the exception. The elaboration of anti-substances in response to a cancerous infection is correspondingly defective, no recognisable immunity becomes established, and spontaneous recovery is exceedingly rare. The fact that the infecting cells of cancer claim kinship with the infected organism may be the cause of the deplorable uniformity with which untreated cases progress to the inevitable end.

The origin of the infective cells.—The probable origin of infective tumour cells within the animal body is indicated by certain biological considerations which we can only briefly pass in review. In the first place we note, from clinical observation in man and from the experimental propagation of Jensen's mouse tumour, that cancer cells are endowed with great vitality and longevity; that, indeed, they appear to possess a reserve of vital energy in excess of that retained by the natural tissues of the body. The second point is that in their manner of growth cancer cells appear to be liberated from the conditions that regulate normal tissue development, that they are a law unto themselves, that they form independent and autonomous growths equivalent to a new individual or rather to a swarm or brood of new individuals parasitic upon their host. Hence, two of the first questions that present themselves are: "Whence this vitality?" and "Whence this autonomy?" A sudden increase of vitality among higher animal cells (of which cancer cells are but a particular variety) is naturally effected by the conjugation of two mature reproductive cells of opposite sex. No other circumstance, so far as we know, is adequate to initiate that new generation of cells which we recognise as a new and independent individual and which alone is endowed with an accession of vital energy. In the higher animals and plants this process of cell conjugation does not take place except between cells specially set apart in the reproductive tissues and specially prepared by a succession of peculiar nuclear divisions, termed maiotic divisions. These nuclear divisions are of so definite a character that they are unmistakeable, and, with a few recognised exceptions, they make their appearance only in the reproductive tissues and only in the cells which are attaining maturity. Now these distinctive forms of nuclear division may be encountered in the dividing cells of early cancerous growths (Farmer, Moore, and Walker). You will at once recognise that this is a most significant circumstance, indicating, as it does, that the cancer cells have assumed one of the fundamental characters of reproductive tissue and that some at least have undergone a process analogous to that which in the reproductive tissues of higher animals is universally found to be an invariable preliminary to cell conjugation. This analogy is reinforced by the further observation that the "cell inclusions" of many cancer cells closely resemble bodies which naturally make their appearance within certain reproductive cells at a certain stage of development (Farmer).

Again, the laws of natural growth are very definite for each tissue and the special laws of any one tissue appear to be equally impressed upon all the cells that develop from it and to form part of their natural heritage. But in the unnatural growth of cancer there is the anomaly of cells descended from tissue cells but growing at variance with the conditions that regulate the development of the parent cells. The only consistent biological explanation of this independence and autonomy would be that the cells differentiated off as early cancer cells should conjugate with other cells inheriting and conforming to other conditions of growth. A truly remarkable fact in the life-history of cancer is that such a process suggestive of cell-conjugation has actually been observed. At all events, an interchange of nuclear matter, which may be regarded as equivalent to conjugation, has been shown to take place between developing cancer cells and emigrated leucocytes (Farmer, Moore, and Walker), and it has also been demonstrated that the leucocyte is peculiar among the normal non-productive cells of the body in having already undergone nuclear divisions peculiar to cells undergoing preparation for conjugation (C. E. Walker). It is possible, therefore, that the fully developed cancer cell may be the offspring of a fixed tissue cell and of a wandering leucocyte, both cells having undergone the nuclear metamorphoses of reproductive tissue. Should this be so it is only reasonable to expect that the resultant cancer cell should participate in the varied capacities of its twofold heritage. Hence may be the reason why the cancer cell, while retaining many of the structural features of the tissue of origin, has come to acquire in so high a degree the additional capacity for wandering, for infiltrating, for infecting.

To recapitulate, then, we find that certain biological phenomena emerge from this recent work on cancer. We find that certain forms of nuclear division appear early in cancer cells, that such nuclear divisions are found only in cells of reproductive tissues preliminary to maturation (and in leucocytes), and that nuclear exchanges (conjugations?) take place between wandering leucocytes and developing cancer cells. Now, can we go further? Can we point to any condition which might predispose a group of tissue cells to assume the character of reproductive cells? As a matter of fact, there is evidence that two conditions are commonly present—one general and the other local—both of which may possibly influence this transformation. The general condition is a chemical change in the reaction of the body fluids. It has been shown that developing cells may be induced to undergo increased and abnormal nuclear divisions when the chemical reaction of their environment is altered and when, in particular, the alkalinity of the medium is increased (Moore, Roaf, and Whitley), and there is evidence that the body fluids of a cancer patient commonly exhibit this increased alkalinity (Moore, Alexander, Kelly, and Roaf). Hence it may at least be said that the body fluids of a cancerous subject are commonly in a condition which independent biological research has shown to be favourable to abnormal nuclear transformations.

The local condition is indicated by the fact that the primary appearance of cancer in any tissue is most frequently associated with the senescence of that tissue. This is not strictly the aging of the tissue but the advent of the period of its functional desuetude. Of the many factors that may be supposed to influence the appearance of new growths the senescence of the tissue of origin is probably the least variable. In all probability, too, the influence of local irritation is exercised in the induction of premature senescence. It is, therefore, not improbable that in some way the senescence of the tissue is related to the appearance of reproductive divisions in certain cells. It is not impossible that, as the period of functional activity draws to a close, the tissue is induced by some obscure biological stimulus to make preparations for self-propagation, which preparations we may designate unnatural or perverted, since they occur in cells not specially set apart for reproduction but which may in reality be the natural expression of a fundamental biological law. It may be that at the root of the cancer process there is this inherent paradox that in trying to achieve immortality for the cells of one tissue it precipitates the death of all.

THE TENTH CONGRESS OF THE PIROGOFF SOCIETY.—The tenth Congress of the Pirogoff Society, a society of Russian medical men, has just been held. About 1000 medical men were present, besides about 2000 invited guests. The President of the society, Professor Rein, opened the proceedings and the President of the congress was chosen in the person of Professor Salasckin, honorary president of the Women's Medical Institute, after which the congress divided into groups to discuss special subjects. It on this occasion celebrated the twenty-fifth year of its existence. The course of its deliberations does not appear to have been marked by any specially noteworthy event and the series of sittings was closed quietly. It was decided to convene the next congress in 1909 at Odessa.

BRITISH HOME FOR INCURABLES.—A festival dinner in aid of the British Home and Hospital for Incurables at Streatham was held at the Prince's Restaurant, Piccadilly, on May 28th, when Lord Cheylesmore presided. In proposing the toast of "The Hospital" the chairman urged the need for wider support from the public. The benefits conferred by the institution were far-reaching and those who received the benefits of the charity were suffering through no fault of their own from incurable diseases. Canon Fleming said that the charity was doing a really pathetic work which commenced where the metropolitan hospitals left off. The British Home for Incurables, which was instituted in 1861, assists those of the middle class who have formerly lived in comfort and respectability but who have been reduced by incurable disease. Besides providing a home for those suffering from incurable disease, it gives pensions of £20 a year to those who are incurable but not wholly destitute, and who desire to reside with their friends. A sum of £15,000 a year is needed to pay the monthly pensions and to maintain the home. Since the institution of the charity, 330 incurable cases had been received in the home and 968 persons had received pensions of £20 a year. Subscriptions and donations amounting to £2345 have already been received as a result of the dinner.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.[1]

BY SAMUEL SLOAN, M.D. GLASG., F.F.P.S. GLASG.,
CONSULTING PHYSICIAN, GLASGOW MATERNITY HOSPITAL; CONSULTING PHYSICIAN, GLASGOW HOSPITAL FOR WOMEN; EXAMINER FOR TRIPLE QUALIFICATION, GLASGOW AND EDINBURGH; FORMERLY EXAMINER, GLASGOW UNIVERSITY, ETC.

ON the introduction of high-frequency currents into medical practice a great, if not the whole, impetus came from D'Arsonval's laboratory experiments. So much did the results obtained by him lay hold upon the medical mind that men of even ordinary enthusiasm were carried away by them. What, it was asked, could high-frequency currents not do? Whilst we were assured that no harm could result from these currents we were told that by their use blood pressure fell, and then rose, remaining at a higher level, that the amount of urea was increased, that the quantity of urine became greater, that the relation of the purin bases to the urea more nearly approached to the normal where the relation had been abnormal, that the amount of exhaled carbonic acid was higher, that the muscular system was invigorated, &c. The dramatic physical effects appealed also to the ignorant and the excitable, and so there was a boom in this new marvel of therapeutic potency. The whirligig of time, however, as usual, brought its revenge. From high hopes as to its possessing a power to do everything, disappointment followed disappointment, till it became a question with honest men whether it was, after all, worth the time and expense. Was it indeed capable of doing anything? True, some wonderful cures were effected—cures where drugs had failed and where prolonged holidays had failed; and the conclusion seemed justified that, after all, there must be something in it, if only this something could be got out of it. This position of hopeful scientific scepticism was my own, after one or two years' experience of high-frequency currents.

The original experiments on its efficacy on the rabbit, the mouse, and the man in the laboratory had been announced in every text-book, new as well as old. I grew tired of this reiteration and asked myself what physiological effects this treatment might have on the man in the street or the invalid at home; not the physiological effects in health but the physiological effects in disease. When are these therapeutic? When are they pathological effects? How do they act not only on the same patient or in the same disease but in the same disease and the same patient in different conditions of that patient?

The question to be solved is, Why are such gratifying results obtained in some cases and why are the results so disappointing in others? The swing of the pendulum in this case must not damp us. We are all familiar with this stage in the evolution of scientific medicine. Let us simply continue to labour and to wait. My researches, in my opinion, justify me in looking towards the future of electro-therapeutics with more confidence than ever, and with the conviction that we are only now on the fringe of great possibilities. This desirable future will come all the sooner if we, individually and as a society, continue not only to wait but to labour, measuring, measuring, measuring. The early part of my work seemed to promise labour only. I seemed to be merely recording and to be unable to see any useful results from these records. They seemed either to disprove my previous assumptions or to contradict each other. Patience, however, occasionally converted a puzzle and an apparent contradiction into a new discovery, or at least a new theory which sometimes reconciled previous seeming contradictions. Science, like art, is long and life's opportunities are few, so I am, after one year of investigation, able to indicate only some of the physiological effects which in my experience have resulted from these currents in disease. I hope you will test my facts and criticise my inferences.

There has been much stir in our society and in medical journals regarding the question of restriction of electro-therapeutics to members of the medical profession. In the interests of our profession and of the public I sympathise with this movement; but partly from a natural anxiety to be always strictly fair towards rivals and opponents I have never had any strong feeling of opposition towards these unqualified practitioners. I have little fear that our craft may be endangered by them. Let us only do our part towards the public with the same amount of zeal with which some of these unqualified operators do their work, and with all the advantages of scientific training and clinical experience on our side the victory is sure in the end to be ours. I feel inclined to leave the public to find out the difference between us for themselves. I confess that I am often so disgusted and impatient with their credulity that I am tempted to say, as was said of Ephraim: "They are joined to their idols, let them alone." Another word I would say regarding the illegitimate practitioner of electro-therapeutics. Before we attempt to remove the mote that is in his eye, let us make sure there is not one quite as large in our own. If he is zealous in his work and honest in his motives, and if, believing in himself, he feels proud of his many cures where "the Faculty" have failed—and in all fairness we must admit that this was often the case in the past, when electro-therapeutics was looked upon less kindly than it now is by the profession—let us not too readily thank God that we are not as he. Let us see, with all our advantages, that we are more scientific in our methods than he is. If, instead of being scientists, we are only artificers—mere switch-pullers indeed—let us see to mend our ways, and having ourselves a high ethical standard, electro-therapeutics will through us attain to its true and honourable position, whilst we as electro-therapeutists will gain, in the highest sense of the term, in due time. In one point the unqualified and the legally qualified practitioners are alike, and in the present unstable position of electro-therapeutics this is pardonable—nay, it is necessary. Both are, and must be, empirics in the proper and original meaning of the term; both find by experience that electricity in certain forms cures or ameliorates certain diseases or disorders; neither can say exactly how. Of how many of our drugs may this not be said? We, however, must not remain content with this. Ours is to reason why and to find out, if at all possible, why the same treatment sometimes does good, sometimes harm, and sometimes neither the one nor the other where circumstances are apparently similar. Since the date of introduction of the galvanometer much has been done in a scientific direction. The physiological action of electric currents can now be determined more readily, and than the determination of the physiological effects of electric current in disease no work can be more profitable and more interesting. The field is large and the work might well be apportioned amongst the members of this society. For this purpose a committee of investigation might be appointed and valuable work might be done.

Cardio-vascular system.—Few subjects have occupied the time and attention of medical scientists during the past few years more than that of blood pressure, and I have read almost everything that has been written on the subject in our medical journals. Writers differ in their mode of investigation, and, as usual, in their conclusions, yet all have agreed on the importance of this subject. I know, however, of no one who has made independent investigations and has published details of his original research in this department of medicine, from the point of view of electro-therapeutics as apart from electro-physiology. What has impressed me most of all in my study of blood pressure literature is the almost universal dread, expressed or implied, of high blood pressure. It has seemed to me to be something of a bogey to many. Only a few writers have mentioned the importance of having in certain cases a high blood pressure. One of these speaking on high blood pressure in cases of nephritis says: "I do not consider high blood pressure in itself a good thing, but I prefer to see it in the subjects of this disease." Another writes: "High blood pressure is possibly in old age a necessity for the purpose of permeating the less patent channels and stimulating more torpid cells."[2] We must not forget that a low or even in some cases a moderately high blood pressure may mean deficient cardiac force.

The more I have considered the question of blood pressure the more I have come to feel that this dangerous desire to have a low blood pressure requires to be checked. We are apt to forget that blood pressure is the product of peripheral resistance and systolic force. With a given peripheral

sometimes striking. One such case will be referred to in the part of this paper dealing with the urinary excretion showing the remote effect of the improved cardiac force on the kidneys. 10. When the blood pressure has been high for the individual's age and there is no apparent disease to account for it, I have observed that after several applications of the current the blood pressure is diminished and there is a corresponding improvement in the pulse-rate. (See Table II. (*b*); also Table IV.)

* Auto-condensation current 500 milliampères for 15 minutes. Age of patient 29 years.

I shall show you presently the effect on the rhythm of the pulse in the case referred to in Table II. 11. In some instances of intermittent pulse—radial only or cardiac as well—the intermissions may diminish or disappear, although as in one case this intermittent pulse had caused anxiety to the patient for many years. Should the intermission have existed for a short period only, as from temporary gastro-intestinal disorder, the intermissions of the pulse may cease after two or three applications of the current; probably from the beneficial effects of the current on the gastro-intestinal canal. A very interesting case of intermittent pulse came under my notice about the beginning of the present researches. The patient was "run down" and she was "nervous." So weak was she and so unstable seemed the cardiac innervation that, although I knew that her object in coming to see me was to get electric treatment, I decided first to put her under bromide of potassium and tincture of nux vomica. At her next visit to me there was no change in the pulse condition, there being still about ten intermissions per minute. Auto-condensation was given for 15 minutes, the pulse-rate fell, and during the following 90 seconds no intermission was detected. The number of intermissions per minute had decreased at her next visit to me four days later, and they again disappeared after 15 minutes of the current. Afterwards the pulse is always noted as regular. A notable condition in this case was that at the early part of the treatment the temperature in the mouth and in the rectum was subnormal, the former being usually under 97° and the latter under 99°. By the end of the treatment the temperature in both the mouth and the rectum became nearly normal.

I think after what I have said regarding the tonic effects of high-frequency currents on the heart I need hardly adduce further evidence of my contention. I have dwelt on this fully because I consider it of the greatest importance, and I think you will agree with me in this. As bearing on this, however, and also on the much-debated question as to the comparative value of the living fingers as against dead, though mechanically more perfect instruments for gauging the condition of the pulse, I may say that the only times I have been impressed with the fact that I was having under my finger a full pulse, as a contrast to what it had been before, was at the close of an auto-condensation and before I knew that my watch and my sphygmomanometer were going to register a lower rate of pulse and a higher blood pressure than before the application of the current. One other point I shall merely mention. Where the pulse is variable before the current application it may become quite regular and steady immediately after. On one occasion the rate varied between 70 and 84 per minute, whereas it was 78 and absolutely steady in its rate immediately after the couch treatment. Some confusion in judging of the influence of the current on e blood pressure is apt to arise where the effect of immediately preceding exertion or excitement has been to raise the blood pressure and to lower the pulse-rate or raise it before application of the current. In the former case the heart has been quite able to respond to the exertion and so becomes slower. In the latter it has not, but has to beat faster on account of the fatigue. (Fig. 2.) If no change has taken place in the pulse-rate—this having been normal before—a good opinion may be formed of the cardiac force. (See Table V.) This case and cases where the pulse-rate is high, owing to nervous dread of the physician, show the importance of allowing sufficient time for restoration of the cardio-vascular *status quo* before any conclusion can be come to regarding the effect of the current on the blood pressure and on the pulse-rate in any particular case. If a

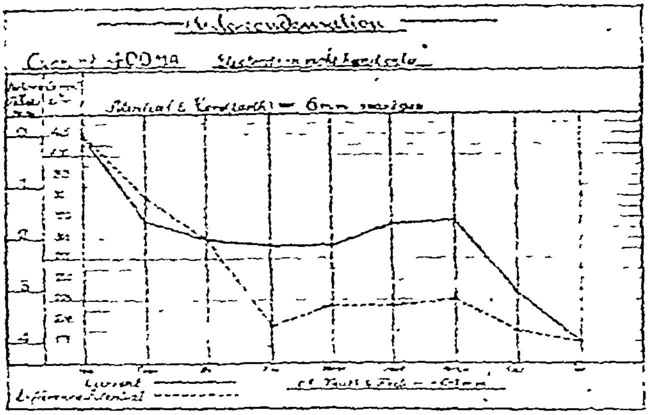
rise of blood pressure and a fall of pulse-rate result from previous exertion a fairly good dose of the current may be given, the final result being probably a lower pulse-rate, with no change in blood pressure. In the case shown in Fig. 4 the tonic effect on the heart is evidenced by a lowering of the pulse-rate without any reduction of the blood pressure.[4] If, however, a rapid pulse be the result of very slight exertion and the blood pressure not have been high, danger may follow even a moderate dose, unless the time be materially shortened (Fig. 2). Should the pulse rise as soon as the current is turned on the patient if asked will probably complain of faintness towards the end of the application, there being a delay of a few minutes in the increase of the cardiac force. The tonic effect on the heart, however, will appear later by the fall in the pulse-rate and the rise in the blood pressure. I may mention here incidentally that in my experience the best results from electric treatment in any form are obtained after all the benefit possible has been derived from drugs and these have failed materially to benefit the patient and when sufficient rest has been taken before each application and for an hour or so after. The best time for a change of air so as to complete the recovery is after the conclusion of the course of electric treatment.

FIG. 5.



Immediate thermic effects.—We are all much indebted to my fellow-townsman, Dr. W. F. Somerville, for his investigations into the problem of surface heat production as a result of high-frequency currents. These are so complete and so firmly established that I need not dwell on them, nor trouble you with my own results more than is necessary to prove what, in my opinion, is the cause of them, and to show that these thermic effects are in no way physiological, but purely physical. For examples of local rises of temperature see Tables VI. and VII. The difficulty of determining the physiological production of heat is stated very clearly by Waller.[5] He says: "By the thermometer we ascertain the temperature of the body, not the amount of heat that it produces or loses. The thermometer gives no measure of the activity of heat production, nor even any positive indication that it is above or below the normal. This must obviously be so when we reflect that the amount of heat in a given body and consequently its temperature, is the resultant of two factors—heat production and dissipation—either or both of which may vary. Theoretically, of course, temperature varies directly with the amount of heat produced and inversely with the amount of heat dissipated, but practically the thermometer does not show whether more or less heat is being produced or dissipated." We are thus left in great part to infer a heat production in the blood by these currents rather than to test it by the thermometer. Here let me state what may not have occurred to some of you, that whilst the rectal temperature is the internal temperature proper, being that of the large splanchnic storehouse of heat, that of the mouth, as pointed out by Haig, is a peripheral temperature. On starting my investigations I allowed too little time for heat distribution consequent on the recumbent position of the patient. In fact, I did not know of it then. When I found, therefore, that at the end of the séance the mouth temperature had risen on an average one degree and the rectal had fallen one degree I came to the conclusion that this was the effect of the current, by relaxation of the peripheral vessels. In one instance—a case of nephritis—exactly the opposite change had resulted, why I cannot tell; but amongst the many I have tested it is the only exception. After some control experiments I discovered that the transfer of heat from the internal to the peripheral circulation was natural and in no sense electro-physiological. A considerable amount of time, I find, is required to bring about this state of heat equilibrium, something like from 30 to 40 minutes. This gives time also for determining to what extent heat reduction is taking place. This latter will depend on previous exercise and the time of the patient's last meal. Physiologists are evidently agreed that the greatly

[5] Human Physiology, third edition, p. 22[illegible]

reduced morning temperature, internal and peripheral, is wholly due to diminished heat production consequent upon long rest. If the blood temperature as ascertained in the mouth and rectum has been diminishing before the current was applied and is found to be stationary during the time of the current, the natural inference is that the current has had some share in this by causing increased heat production. My researches have pointed in this direction, but I have little of definite proof to bring forward in support of it. Waller's statement may explain this. It will be a natural inference also that the heat distribution I have spoken of will account for the rise in the surface temperature throughout as well as in that of the mouth. There is evidence of this contention in the heat tables I now show you, as an explanation of some at least of Dr. Somerville's results. In no case where I have allowed sufficient time to elapse before turning on the current has there been anything like such a rise as he, in some cases, has found. (See Tables VI., VII., and VIII.)

Temperature of room 63°, rising to 70°.
Electrodes in both hands.

It will be noticed that the greatest increase of heat is near the electrodes, and this increase of heat diminishes in amount in proportion, as a rule, to the distance of the parts tested from the electrodes. It is plainly not blood heat, but only surface or superficial tissue heat. Table IX. is a good example of this, the electrodes having been in the right hand and on the left foot. In some of my observations the temperature in the axilla is actually higher than that of the mouth. The only time I have ever observed this, apart from the action of the current, was when a patient came to see me one cold night and I found the temperature in the axilla 98°, whilst that of the mouth was 97·7°. This, however, was obviously due to the fact that he was in part a mouth-breather and had left at home his artificial teeth, as these were uncomfortable. As soon, however, as the warm atmosphere of the room had time to tell the mouth temperature became 98·6°. Now, how are these increased surface temperatures caused? I have pointed out that they are greater the nearer the parts tested are to the electrodes, and you will see that this is, by physical laws, just what might be expected, since the current to earth is greatest there and the local heat will be directly proportioned to the square of the current. It must be borne in mind that the quantity of the electricity in the case of the static form is proportioned only to the capacity of the part; whereas in high-frequency applications the current decreases in proportion to the distance of the parts from the electrodes and to the difference of the potential between these and the points from which we are measuring it. (See Fig. 5.)

* Auto-condensation current 500 milliampères for 15 minutes. Observations begun after having been one hour in warm room.
Electrodes in right hand and on left foot.

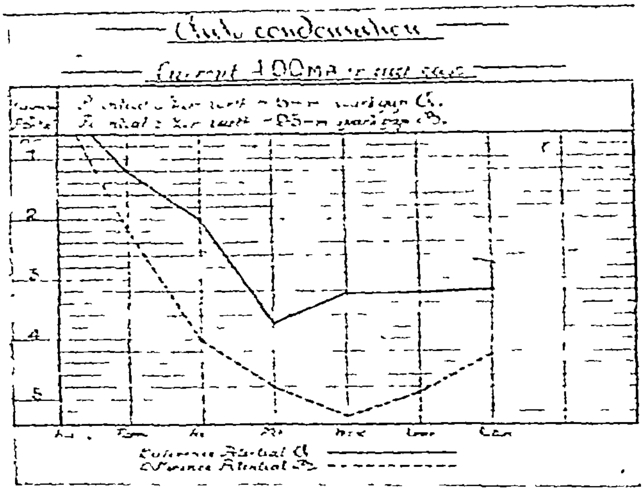
The heat production is the product of the resistance, as measured by the difference of potential, into the square of the current, and the closer these points of potential difference are to each other in proportion to the amount of potential difference the greater will be the heat concentrated there. This is, of course, a purely physical law; and it can easily be seen that, considering the enormous ohmic resistance of the dry skin, this resistance might quite equal a spark-gap of one to two millimetres between the hand and the forearm, as you can see is the case in some of the charts. That distance, as well as ohmic resistance, determines the length of the spark-gaps, and therefore the amount of the current from various points to zero is shown in Fig. 6. Of course, we must remember that although the heat production is directly increased by the potential difference, yet as this increases it will be seen that the current decreases, and so the heat production is less in spite of the resistance being greater, since the current has more influence than the resistance in causing heat.

I need hardly say anything as to how the amounts of this potential difference and current to zero are obtained. The points from which the potential difference is to be measured should have a metallic connexion to either side of a spinthermeter for the former. The current to zero is measured by making a metallic connexion from any part to earth with a milliampèremeter in series. With both hands on the ordinary electrodes it would be seen that the largest amount of current is, as might be expected, from the hands. The next in amount of current of those measured is from the forearm, and the potential difference between the hand and the forearm is quite considerable, varying from one millimetre to two millimetres, so that nearly the full amount of the current from the hand must act on the wrist and lower forearm. (See Fig. 5.) That the lines of the potential difference and of the current to zero in this chart do not quite run parallel is due, I suspect, in part to the fact that all the potential difference records are taken at one time and then all the current records. This will result in the points of each region from which the readings are taken not being exactly the same. The potential difference and the current may differ in various cases, but though this will in part depend on the ohmic resistance it also depends, at least in the case of the potential difference, on the initial total potential difference—that is, length of spark-gap from hands to earth, the same quantity of current being obtainable from the same apparatus and on the same individual by different arrangements of solenoid and spark-gap, but with a different amount of total initial potential difference to earth. (See Fig. 7.) Query, what, if any, difference therapeutically will there be from the same amount of current but at different voltages? This I have not had time to test.

I have no doubt that some of the rise of temperature in the mouth and in the rectum must be electro-physical, but how much it would be difficult to say. I should expect, however, that this would tell more on the mouth temperature than on that of the rectum, when the electrodes are grasped by both hands. Like Dr. Somerville, I have noticed that the increase of heat on the left forearm is less than that on the right. The cause of this I find is that the resistance is usually greater, and the current to zero less, in the left than in the right forearm. For obvious reasons the reverse would probably be the case in left-handed people.

Penetration of the currents into the deeper tissues.—I have already taken up so much time with the part of my thesis bearing on the cardio-vascular system that I must be brief with the remaining departments outlined in my synopsis. On another occasion I may return to them. It has been generally assumed that high-frequency currents are confined practically, if not wholly, to the surface, and that their physiological effects arise from their action on the peripheral nerves and the peripheral circulation. Dr. H. Lewis Jones, in his admirable text-book on "Medical Electricity," contests the truth of this assumption, basing his argument on the physiological results being such as to require for their explanation a deeper action of the currents. My researches have quite convinced me that there is abundant evidence of Dr. Jones's contention from the electro-physical standpoint. Before going into this matter, however, let me say that if anyone doubts the fact that these currents traverse the neuro-muscular apparatus, let him, with one hand holding one of the usual couch electrodes, place another electrode held by an insulated handle on the upper portion of the sterno-mastoid muscle and with metallic connexion to the hand electrode, a small spark-gap only intervening, and he will have sensible demonstration of the fact. An objection to this will probably be made that it is the spark which is causing this and not the current from the hand to the neck. Well, let anyone try this experiment without any flow of current by letting go the hand electrode but retaining the spark-gap to the connexion between the couch terminal and the neck, and he will find that so long as he holds the hand electrode so long will there be muscular response, but as soon as he lets go the handle no muscular contraction will occur, although the connexion still exists. Let the gap be so wide, however, that no sparking occurs, then no muscular contraction occurs. The current from the hand to the neck requires to have its potential and the amount of its current disturbed by the varying condition of the outer spark-gap circuit. If an additional argument were required that it was the current from the hand to the neck which was causing the disturbance, it might be found in the fact that as soon as the neck electrode is applied contraction of the muscles of the forearm is set up as well. Another objection which might be raised is that the current causing the muscular contraction is not a pure high-frequency current. If by that is meant that when high-frequency currents are pure they do not cause muscular contraction, I admit this. All the same, however, they are high-frequency currents, the only difference being that at the time they are suffering from a frequent change of potential, through the irregular action of the spark-gap, just as the unidirected current causes muscular contraction only when its potential is changed. In the latter case, however, it is not contended that since there is no muscular contraction during the steady flow of the current there is therefore no current reaching and passing through the muscle. The electro-physical evidence will, I think, appeal to you without much argument from me. A mere statement of some facts, indeed, and an explanation of these by means of Fig. 6, will, I think, satisfy you.

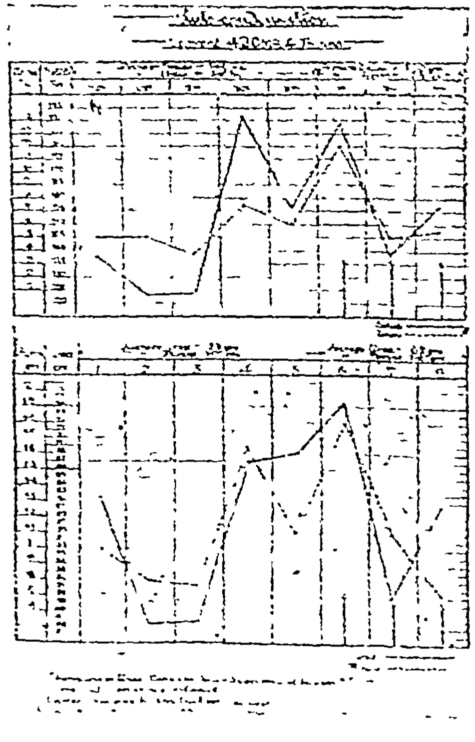
FIG. 7.



I have referred to the fact that the potential difference varies according to the resistance and in proportion to the distance from the entering current. You see that it may amount to about one millimetre at the forearm, two millimetres at the axilla, three millimetres at the waist, three millimetres at the groin, and four millimetres at the foot. If you examine this chart, however, you will find that the potential difference from the hand to the mouth is practically the same as that from the hand to the rectum; now the potential difference between the neck and the groin is five times as great as that between the mouth and the rectum: that is to say, the resistance and the distance between the mouth and the rectum are not those by the chin, neck, breast, and abdominal walls, but by the gastro-intestinal tract. Again, the potential difference between the axilla and the groin is less than that between the axilla and the waist. Why, indeed, unless the current has gone from the axilla to the groin not simply by way of the body wall but also by the gastro-intestinal canal. I have come to suspect indeed that it takes an even easier road—namely, by the thoracic and abdominal viscera direct, as well as by the gastro-intestinal tract. For if by the latter route only, then, though the ohmic resistance is not great, it is greater than that of a No. 14 copper wire, and the distance is quite as long as 25 feet. Yet we see how large a drop of potential this wire caused. (Fig. 6.) The amount of current is zero at the mouth and at the rectum is almost as if there were different parts of a metallic plate over which the current is flowing easily. Since the current is thus seen to be acting on the whole lining membrane of the alimentary canal there is no wonder that this electric energy has an influence on the appetite and on the general health.

Effects on renal excretion.—My researches in this department have, like those in connexion with the cardio-vascular system, led to a good deal of confusion and uncertainty; and although in the case of the latter I think I have been able to bring some order out of this confusion, I am not quite sure that this has been so in the present department of this work. It will readily be seen that the difficulties are greater. In the laboratory experiments absolute rules as to diet can be, and must be, enforced; whilst in the case of patients such rules are difficult, if not impossible, to enforce, and, if possible, not generally desirable; the tastes

FIG. 8.



This figure is meant to show the immediate effect of the current on the urine. Five preliminary investigations are made on the urinary excretion of four hours, namely, from 10 A.M. till 2 P.M. Thereafter the current is applied daily at 10 A.M. and similar measurements of the urine are made to determine the changes, if any.

and habits of the patients forbid this in the interests of recovery which must be the principal result aimed at. Again this variety in the matter of diet, exercise, &c., brings about such a daily variation in urinary excretions that one day, or even an average of several days, cannot be taken as a criterion; so that the effect of the current may be difficult to detect or measure with any degree of accuracy. It will be obvious, then, that the results of investigations in this department of the subject can only be, in a vague way, of weight. I show you examples which will illustrate these vagaries of the urinary products. (See Figs. 8 and 9 and urine tables.) You will see here that one day more or one day less on either side of the dividing line which indicates the beginning of the electric treatment may quite change an apparently important modification in the one direction into one quite in the opposite. This, however, will hardly account for a steadily maintained change in the direction of the normal for that individual under the influence of the current, where this personal factor can be obtained. (See Table X.) This table shows a steady advance towards the normal; taking as this the urinary excretion of several months later, when the condition of the patient is noted as "very good," though there still existed the kidney disease as evidenced by a trace of albumin being constantly found in the urine. This is only one case but it may be none the less a valuable one. It is one that I have been able to watch and to gauge the progress of with exceptional care and accuracy. In a case like this where so much benefit has followed the treatment the question arises, What has been the primary action of the current? Dr. Alexander Robertson, formerly professor of medicine, St. Mungo's College, was in charge of the case, and I was acting in conjunction with him. It was one of a very slow convalescence from uræmic convulsions. Coma had lasted for about a week; general blood-letting had been resorted to and for some days it seemed impossible for the patient to recover. Convalescence, as I have said, was very protracted and after ten weeks no appreciable progress was being made, the pulse remaining between 96 and 102. No medicine seemed to have any influence on the pulse-rate. At this stage I suggested high-frequency treatment. I said that I felt sure it would do some good; whether by influencing the general health through the kidneys or the latter through the former I could not tell. It was purely empirical knowledge only I could speak from then. Dr. Robertson agreed to the trial. We decided to stop all medicines and simply to note the condition of the patient from day to day, allowing ten days for this before beginning the electric treatment in order that we might be able to eliminate any source of error in the final result. The effect on the pulse-rate was marked. Whereas during the ten days preceding high-frequency treatment it varied between 96 and 102, it came down to 83 after the third application, practically remaining at 85 thereafter. I have no records in this case of the blood pressure at this stage because this was always taken by means of the Hill and Barnard sphygmomanometer, in which I have explained to you I have no confidence; but later, at about the time this patient's health is noted as "very good" the pulse after rest was found to be 88 and the blood pressure 218 by the Riva-Rocci (Martin) sphygmomanometer at 8 P.M. The blood pressure, therefore, may be taken at the period of convalescence indicated as about 180 to 200, and the cause of the high pulse-rate at that time as the high blood pressure *plus* the cardiac failure, especially the latter.

Ratio of purins to urea = 1 to 32.

Into the question of purins in the blood and their effect on the circulation and on the general health this is not the occasion to enter. I have been studying this question for many years and have made a large number of examinations of urine in connexion with the subject. Whilst Haig may be, I believe is, right in many cases in withholding a diet rich in uric acid, I have come to the conclusion that, in the case of most people, if only the diet is suited to the individual in *quantity* and a fair consideration given to the natural instincts in the matter of appetite, attempts should be made to improve the cardiac force and to set right the gastro-intestinal digestion, leaving the purins to take care of themselves, rather than to try to rectify faults of metabolism by washing out the purins or taking special steps to avoid their intake. I should like to draw your attention to one or two points in this connexion, however, which are illustrated in my charts and tables. In the case of nephritis referred to I found that whilst the 24 hours amount of albumin fell as the pulse-rate fell, the curve of the total purins actually rose. True, the urea was probably rising also; but if you examine Table X., which refers to this case, you will see that whilst the average daily amount of purins in the early part of the treatment was 5·6 grains, that excreted later was 6·5 grains, whilst that at the time of greatly improved health was 7·8 grains. The relation of purins to urea again became lower after the treatment and was again higher at the later stage of improved condition. Probably each man has his own purin ratio, as each one has his own urea factor; and until we can ascertain this for the individual in health it is a waste of time to argue as to the effect of the increase or decrease of the purins excreted on the general health. Look now at Table XI. Here in Case (A) we have practically the

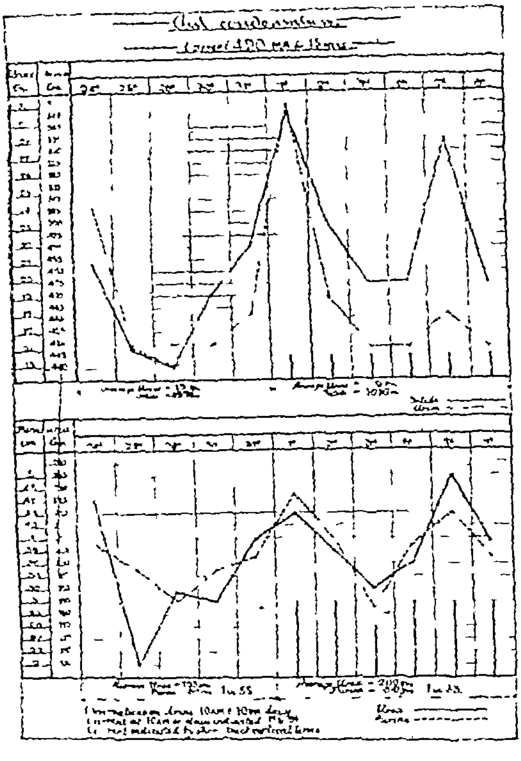
me ratio of purins to urea at the close as at the beginning f the treatment; although the treatment immediately nproved the general health. The same may be said of he case referred to in Fig. 9, where the ratio is 1 in 55 efore and 1 in 53 after treatment; and yet my notes say regarding this case at the close of the treatment: "General condition improved, no rheumatism, no restlessness of legs now." The rheumatic condition must be more than a mere matter of purins. Look again at Cases (B) and (C) in Table XI. and you will find very little change in the purin-urea ratio in either, and yet, in the former at least, the condition improved vastly after the electric treatment. In this Case (B), one of obesity, the urea and the purins have both increased under the treatment. I have pointed out, however, that this is not an invariable result. Indeed, looking at Case (A) you will there see that where a like benefit had followed exactly the opposite had occurred.

FIG. 9.

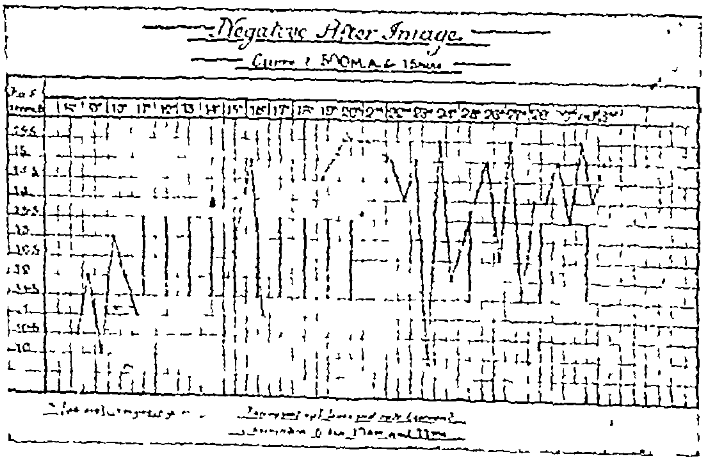


Here measurements are made of the total urine from 10 A.M. till 10 P.M. for five days before and for six days after the beginning of the electric applications, these being daily at 10 A.M.

I have left myself very little time to speak of the Joulie urinary coefficients. Let me just say that by this is meant the actual amount of phosphates of the urina sanguinis per litre per cent. specific gravity, divided by the total acidity per litre per cent. specific gravity. The normal figure for the phosphates, reckoned as P_2O_5, is 11·17, that of the acidity 4·55, the ratio being thus 2·45. From the variation in these figures Joulie draws important conclusions regarding the metabolic processes and the indications for treatment. Whether electric treatment by high-frequency currents would modify these figures I have not yet settled in my own mind, though I have made numerous experiments in this direction. I may return to this subject on a future occasion.

Retino-cerebral mechanism.—I have considered the physiological effects of high-frequency currents from the points of view of the cardio-vascular, thermo-genetic, gastro-intestinal, and renal systems. Can any of these, or all of them put together, explain the various signs and symptoms we know to expect from this treatment? I am sure they cannot. They give no explanation of certain sensations remarked upon by patients when undergoing auto-condensation treatment. One patient will say that the after-effect is a sense of "comfortable weariness in contrast to fatigue or faintness." Another I have heard remark: "I feel for an hour or two after a restful weariness which is just lovely." One lady, after the vacuum electrode from the high-frequency solenoid had been applied to the supra-orbital region for neuralgia, remarked to me the following day: "I don't know what you have done to me or how you have done it, but since yesterday a load has been lifted from my mind and all my cares are gone." For years this lady seemed to have a weight of care on her and there had I knew been much cause for this. Yet at her subsequent visits and until I last saw her she declared that her burden of mental distress had not returned. Unfortunately, this is an exceptional case; but it will serve as an illustration of the point I wish to enforce—viz., that some action on the central nervous system takes place under the therapeutic use of these currents. How is this effect to be seen or measured? We cannot see what is going on in the brain, but we may see and measure what is going on in the retina, which, after all, is a prolongation of the brain. What is called the "after-image" may by the measurements of its duration give us some indication of the condition of the retino-cerebral mechanism. Physiologists whose works I had consulted declare that the duration of this after-image is proportional to the cerebral fatigue present. Haig maintains that the undue prolongation of the positive after-image is due to a state of collæmia of the capillaries of the retina, and this condition, according to him, is caused by excessive uric acid in the blood, which again is a cause of cerebral malnutrition. I tried to measure the duration of the positive after-image on myself but gave this up for several reasons. The exposure of the eye to a strong light for several seconds was uncomfortable, if not mischievous; besides, it seemed impossible for me to fix a moment of time in the course of its disappearance as a measure of its duration, and further it continually eluded me in my endeavour to keep it stationary. I then decided to measure the duration of the negative after-image as an index of the cerebral fatigue. I soon, however, had reason to doubt whether this, the duration, was directly proportional to the cerebral fatigue, and I began to suspect that it was rather inversely proportional to this, since the fresher I was the longer did the after-image remain. I also noticed that the duration was longer in the morning than at night and longer with the young and the strong than with myself. On satisfying myself as to these points I consulted various other authorities and discovered that the opinions of physiologists were about equally divided on the subject of the after-image

FIG. 10.



as an indicator of the retino-cerebral condition, some maintaining that its duration was directly proportional to the fatigue, others that it was inversely so.

Let me here explain, for the benefit of those of you who may not have studied this subject, the nature of the negative after-image and the means for accurately measuring its duration.

(*Explanation given and the means of observation shown.*)—My experience has led me to the following conclusions: 1. That the duration of the negative after-image is different in different individuals. 2. That in the same individual it differs according to the state of the health, being longer when the person is well and fresh than when ill and fatigued; according to the time of day, being, at least in my own case, longest just after breakfast and shortest at bedtime. I could, indeed, tell with a fair amount of certainty how fit or unfit I was going to be during the day by taking my negative after-image in the morning, and I could fairly correctly gauge what it was going to be when I had finished my day's work. When, by reason of temporary good spirits giving me the feeling of being particularly fit, I expected to find it high in spite of a specially hard day's work, I discovered that this was not the case, the duration being less owing to the previous fatigue. I can with a metronome beating half seconds reckon the duration in my own case to a quarter of a second. A considerable amount of experience is necessary, however, to be able to measure with sufficient scientific accuracy the duration of one's own after-image. Accordingly I have not been very successful with other people; but I recommend the matter to your consideration as interesting and as of scientific value. The examination must take place as near as possible at the same hour, the light must be the same, the distance of the light from the image the same, and the distance of the eye from the object and the image also the same, as well as must the metronome beat at exactly the same rate and for the same number of half seconds before the eye is turned towards the white paper. The image generally appears at once, but with some people there is a delay of a few half seconds before its appearance. With most the image returns two or three times but this is not reckoned in the measurement. Unless the eye be kept fixed on one spot the record is spoiled. Accordingly I have, as you see, fixed a pin in the centre of each paper to keep the eye fixed on, since if it wanders from the spot it was originally fixed on the image at once disappears. Fig. 10 is a good example of the negative after-image record in a case where the benefit derived from the current was most marked. You will observe that the average for the six times noted before the beginning of the treatment is slightly under 11·5, that for the time succeeding the treatment slightly over 14. Note also the effect of fatigue on one occasion and also that, when the duration of the image is ceasing to be so favourable after the treatment had stopped, one application of the current has raised the night record to a higher level than that of the morning of the same day.

Questions worthy of consideration as to future investigations.—1. Do the physiological results differ where the amount of the current is the same but the initial voltages differ? 2. Can any changes in the retinal vessels be observed? 3. What influence may the time of application have with relation to meals? 4. What are the effects of varying doses and duration of application under exactly the same conditions of the patient? 5. What might be the effect of high-frequency currents on the growth or virulence of bacteria, with special reference to those found in disordered conditions of the intestinal canal? 6. What, if any, influence have these currents on the urina sanguinis with relation to the Joulie ratios? Finally, let me again advise the appointment of a scientific investigation committee.

Glasgow.

Welsh Medical Dinner.—The fourth annual Welsh medical dinner was held in London on May 31st, under the presidency of Sir Isambard Owen. There was a good attendance and amongst those present were Sir R. Douglas Powell (President of the Royal College of Physicians of London) and Mr. Henry Morris (President of the Royal College of Surgeons of England). Sir Isambard Owen, in the course of an interesting speech, alluded to the fact that the University of Wales was securing a supplemental charter to empower it to confer degrees in medicine and surgery.

VARIATIONS IN THE AGE-INCIDENCE OF MORTALITY FROM CERTAIN DISEASES.[1]

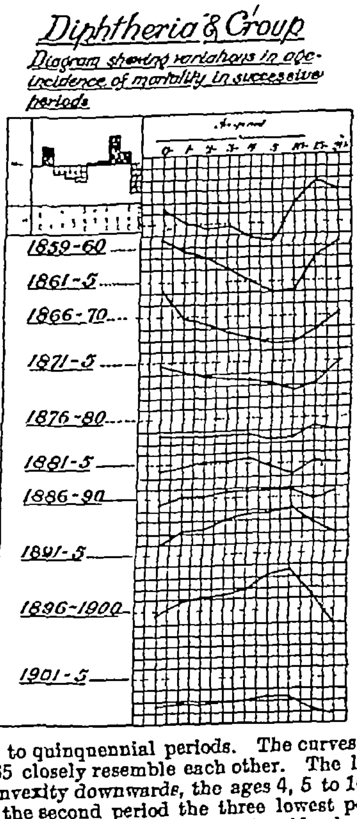
By Sir SHIRLEY F. MURPHY,
MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

At the request of your secretaries I am proposing to submit for your consideration a series of diagrams showing change in the age-incidence of mortality from certain diseases. The subject has been from time to time discussed in reports I have presented to the London County Council, but although it is not entirely new I hope the diagrams will be found to be of sufficient interest to the meeting to justify me in occupying a part of the evening in their exhibition.

I wish, in the first instance, to state how these diagrams have been constructed, in order that they may be perfectly intelligible. The method of construction is the same in each instance. The mean death-rate at each age in the whole period under consideration is taken as a standard, and the death-rate at each age in each quinquennial or decennial period is stated as a percentage above or below the mean of the whole period. Thus the death-rates at the several ages over the whole period are represented by a straight line, and the excess or defect of the death-rates at these ages in each quinquennial or decennial period forms a curved line above or below the mean. It is obvious that by this method any deviation from a straight line represents variation in the age-incidence of mortality.

The first diagram (Fig. 1) which I will ask you to look at is based upon the deaths in London from diphtheria and croup from the period 1859 to 1905. The first period represented by a curved line relates to the years 1859 and 1860, while all other lines relate to quinquennial periods. The curves of 1859-60 and 1861-65 closely resemble each other. The line is bent with the convexity downwards, the ages 4, 5 to 10 and 10 to 15 being in the second period the three lowest points in the curve. The period 1859-65 was one of epidemic prevalence. The next three quinquennial periods are periods of decline of prevalence, but it will be seen that this decline has been obtained not so much by decline at the ages I have mentioned as by decline at ages below and above those ages, so that the line representing the period 1876-80

Fig. 1.



---

[1] A paper read before the Epidemiological Society on March 5th, 1907.

is almost a straight line. The periods 1881–85 and 1886–90 are periods of increase of prevalence and the increase has been much the same at each age, although it will be noted that in 1881–85 the ages 2, 3, and 4 are a trifle above the mean, and in 1886–90 the ages 1, 2, 3, 4, 5 to 10 and 10 to 15 are also above the mean. There is, indeed, a slight tendency in both these periods for the line to become curved with the convexity upwards. In 1891–95 the recent epidemic in London was at its height; there was increase at each age, but this increase was most marked at ages 4, 5 to 10 and 10 to 15. In 1895–1900 there was some decline, but the mortality from this disease was still much above the average, especially at the ages 5 to 10 and 10 to 15. In 1901–05 the death-rate at all ages was lower than it has been since the deaths from diphtheria have been separately stated by the Registrar-General, and the line has now become almost straight, with a slight tendency for the decrease to be less manifested at ages 5 to 10 and 10 to 15 than at the other ages.

FIG. 2.

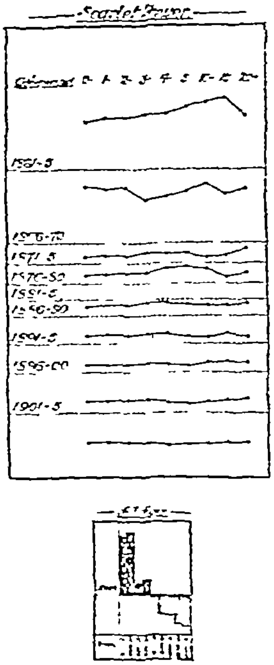


FIG. 3.

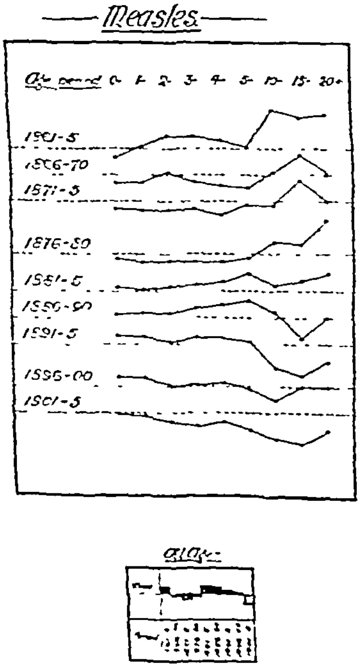

FIG. 4

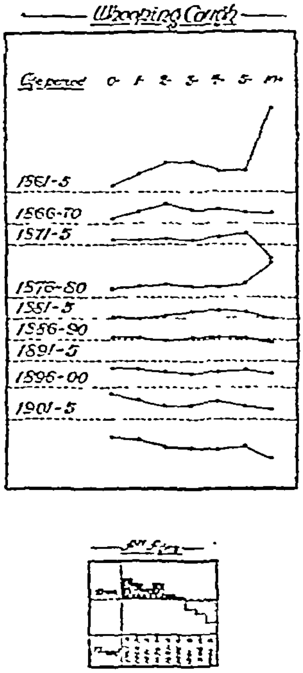

FIG. 5

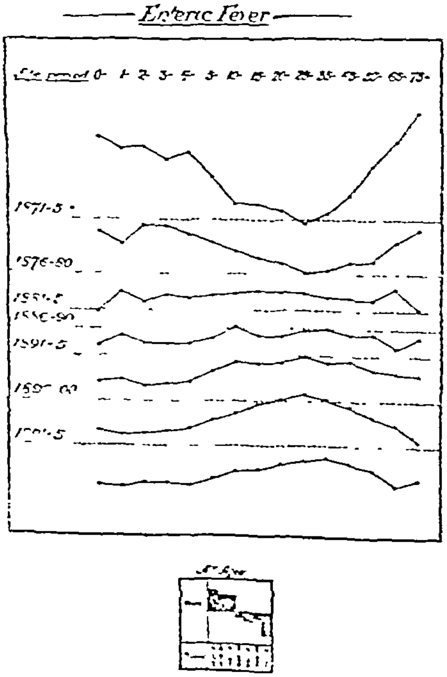
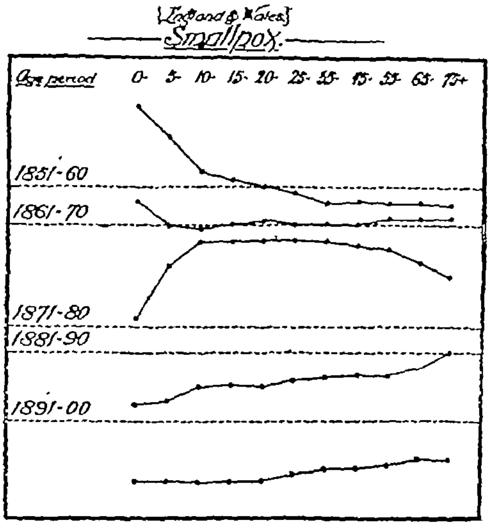
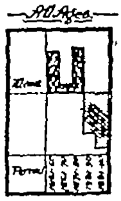


There has, therefore, been a change in age-incidence which there is reason for thinking is rhythmical, but the whole story is not yet complete, for we need the periods 1906-10 and 1911–15, or indeed still later periods, to enable us to see whether the lines which they will provide will resemble those of 1866-70 and 1871–75. Possibly, however, there will be less conspicuous curves than in these years, owing to the greater aggregation of children in school leading to increased incidence of mortality at the school age. It is noteworthy that the increased incidence on ages 4, 5 to 10 and 10 to 15 began when there was decline in the "all ages" death-rate. I think this may probably be a natural increase, although it may have been accentuated by increase in aggregation of children at school. However this may be, I should expect to find the first evidence of recurrence of epidemic prevalence of diphtheria in increase of relative incidence upon the ages 4, 5 to 10 and 10 to 15.

FIG. 6.





The scarlet fever diagram (Fig. 2) is only able to show a story of decline during practically the whole period for which the figures are available. There is, however, a greater tendency for the lines to become straight in the later periods than in the earlier. The line for the period 1861-65 shows greater relative incidence on the ages 4, 5 to 10, 10 to 15, and 15 to 20 than that of any others; and again in 1876-80, when there was some increase in mortality at all ages, this was especially manifest at ages 4, 5 to 10 and 10 to 15. Of course it needs to be remembered that the periods between epidemic prevalences of scarlet fever may be much longer than in the case of diphtheria, and that the time for the minimum incidence on the ages mentioned has not yet come; otherwise a depression of the curve in the last period or two might have been expected; unless, of course, as the result of greater aggregation of children, at ages 4, 5 to 10 and 10 to 15, the depression in the curve at those ages, which might otherwise have occurred, has been obscured. All that can be said is that there is some suggestion in the last two curves of depression at these ages.

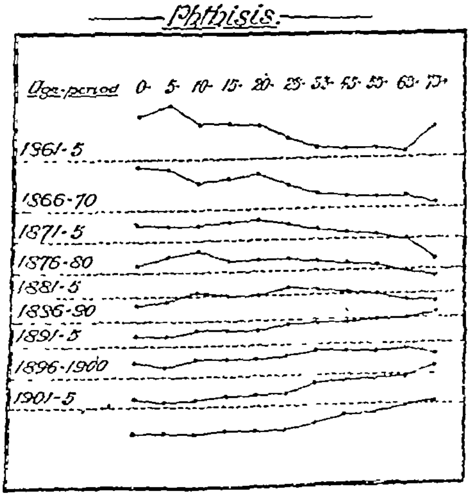
The measles diagram (Fig. 3) tells much the same story. In 1861-65, a period of high mortality, this was exceptionally manifest at ages 2, 3, and 4 (the figures for ages over 10 are comparatively small and no great importance can attach to them). With decline of mortality the line becomes more nearly straight. With increased mortality in 1881-85 and 1886-90 the increase is manifested especially at ages 3, 4, and 5 to 10; and then with decreasing mortality at all ages this special incidence becomes less evident.

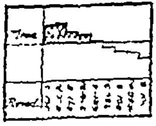
The whooping-cough diagram (Fig. 4) closely resembles that of measles. Here, again, the figures for the higher ages are small and apt to yield exceptional results. With slight exceptions there has been decline in the period represented. The curve which is seen in the line of 1861-65 becomes flattened out in subsequent periods. The small increase in mortality at all ages in the period 1876-80 does not appear to have materially affected the curve of those years.

The diagram of enteric fever (Fig. 5) is interesting because, while there has been decline in the death-rate at all ages during the whole period represented, with very slight exception in 1896-1900, there has been increasingly greater relative incidence on the age-period 25 to 35, and on the ages which immediately precede and follow that age-period. The diagram shows that these ages have not participated in the general decline anything like so much as the others. In the period 1901-05, however, the line is straighter than it was in 1896-1900. Although it is quite conceivable that the age-incidence of mortality from this disease would be affected by alteration in the opportunity for infection to reach man by particular channels, in view of what is seen in the diagrams relating to the other diseases I cannot deny the possibility that this change is a natural variation. It will be recollected that the diphtheria diagram manifested increase of incidence on age-periods 4, 5 to 10 and 10 to 15 with decline of mortality at "all ages."

For the purposes of a diagram representing small-pox mortality I have been obliged to abandon London and to use figures relating to England and Wales, so as to avoid the error which would result from the removal of cases of small-pox from London to districts outside where the deaths were registered. It is, of course, impossible from this diagram (Fig. 6) to learn what is the natural behaviour of small-pox in respect of age-incidence on account of the disturbing effect of vaccination. It is, however, interesting to compare the incidence on the age-periods 0 to 5 and 5 to 10 in the two epidemic periods 1851-60 and 1871-80 and to observe that in the two later decennia, in the absence of epidemic prevalence, the lines lose their curvature and become more nearly straight.

FIG. 7.





The diagram for phthisis (Fig. 7) shows, of course, general decline of mortality from this disease and shows also how much more marked this decline is at the younger ages than at the older ages. It gives no indications of that behaviour of the curves which is noticeable especially in the case of diphtheria, but is suggestive of decline of mortality owing to successive additions by birth of a more resistant race.

The cancer diagram (Fig. 8), based on the figures for England and Wales, is in the main interesting as showing behaviour which, I think, can only be explicable on the hypothesis of change in nomenclature. It will be seen that the incidence on ages below 25 years was in the second and third decennia actually and relatively less than in the first, while on ages above 25 the incidence is increasing. Further, the incidence on ages 25 to 35 is in the second and third periods relatively increasing. In the fourth period the line becomes practically straight, but in the fifth period the incidence on ages 25 to 35 becomes relatively less than on other ages. The actual incidence on ages 25 to 35 has, however, remained practically constant throughout the whole 50 years.

The last of this series is the diagram relating to "all causes" (Fig. 9). It closely resembles the diagram for phthisis, but differs from it in exhibiting a tendency for the mortality of the first year of life to be maintained in greater degree than that of subsequent ages. This is no doubt in some degree due to the mortality from measles and whooping-cough being especially maintained in the first year of life, but is probably largely due to the more complete registration during later periods of deaths of infants who survive their birth but a short time. There is here also the suggestion of the birth in successive periods of a more resistant race.

FIG. 8

Cancer

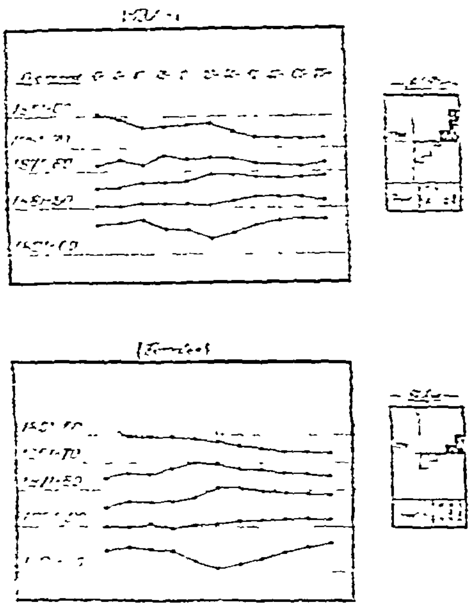


FIG. 9.

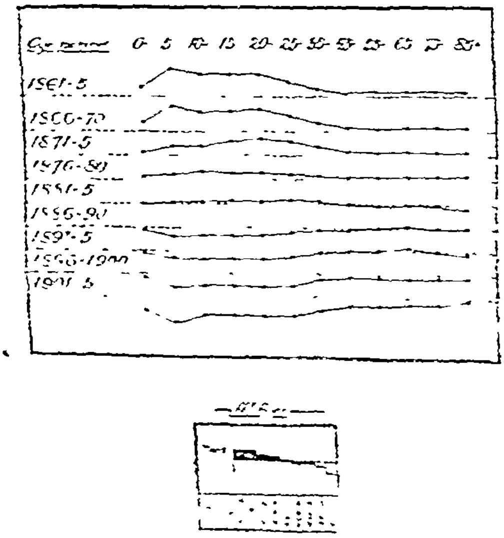
All Causes



I have said little concerning the effect which change of nomenclature, better diagnosis, &c., must have had on the diagrams; and indeed only mention it now to protect myself from the suggestion that I have not had it in my mind. I have preferred to present the diagrams based as they are on the actual records of the Registrar-General. I think, however, in the case of the infectious maladies, scarlet fever, diphtheria, measles, and whooping-cough, that variations in the age-incidence of mortality occur as a natural phenomenon, not improbably as the result of variation in virulence, and affected also no doubt by such influences as difference in opportunity of acquiring infection, and perhaps in small degree by differences in

FIG. 10.

Diphtheria.

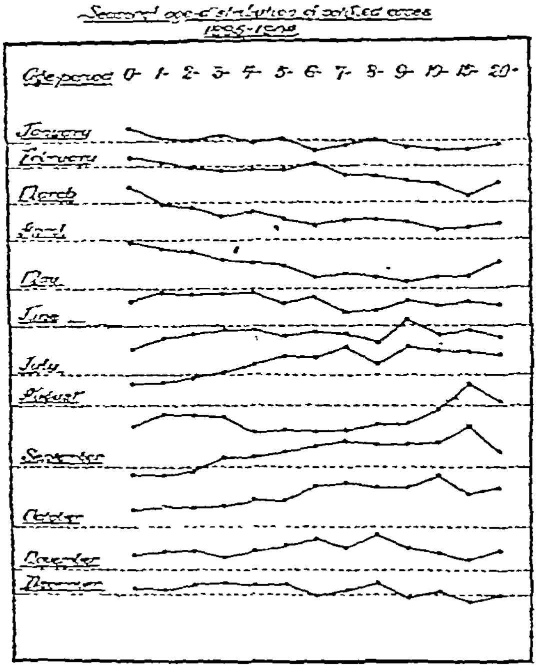


FIG. 11.

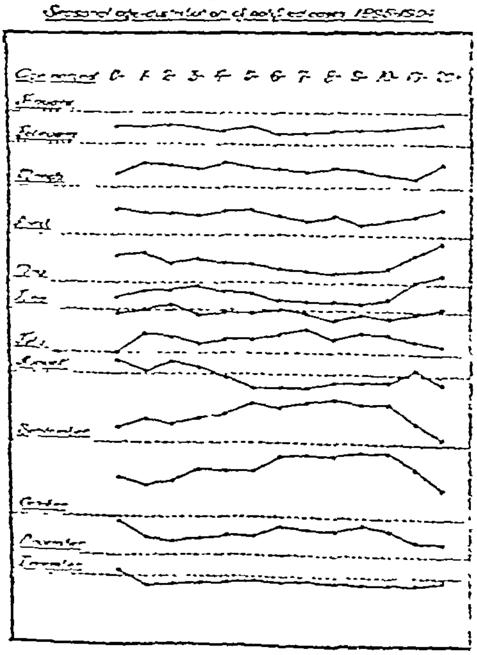
Scarlet Fever



the proportion of persons at the several ages rendered immune by attack in antecedent periods. That these variations are not the same as those seen in the other diagrams tends to confirm this view.

Apart from the variations which occur over long periods variations can also be shown to occur as the result of season. The last two diagrams I have to exhibit show this in respect of diphtheria and scarlet fever. It will be seen that in the case of diphtheria (Fig. 10) the incidence of attack on the ages 5, 6, 7, and 8 increasingly declines until April, after which it increases until August, when the increase is interrupted by the school holiday. It is again manifest in September and October, and then again declines.

The diagram relating to scarlet fever (Fig. 11) shows practically the same behaviour, except that the decline at the ages mentioned is continued to May.

LIGATURE OF THE RENAL VESSELS BY THE TRANSPERITONEAL METHOD FOR THE CURE OF PERSISTENT URINARY RENAL FISTULA,

WITH NOTES OF ONE SUCCESSFUL CASE,[1]

By MAURICE P. HOLT, M.R.C.S. Eng.,
MAJOR, R.A.M.C.

1. *Choice of procedure: (a) nephrectomy.*—In the absence of well-known contra-indications nephrectomy is commonly acknowledged to be a legitimate surgical procedure in certain of these cases. But where there is extensive matting of the kidney and perinephritic tissues to surrounding structures nephrectomy may be extremely difficult or even impossible. The severity of the operation, the risk to the patient from hæmorrhage, shock, and damage to important organs and serous cavities, justify the authoritative admission that the maintenance of good drainage is then the sole resource in the vague hope that at some future and quite uncertain date healing may occur.

(*b*) *Subcapsular nephrectomy;* (*c*) *morcellement.*—In other cases subcapsular nephrectomy, piecemeal nephrectomy or morcellement may be tried, but these operations are often followed by prolonged suppuration or by permanent fistula owing to a portion of renal tissue having been left behind, as it frequently is.

2. *Disabilities attendant on a persistent renal sinus.*—Taking the case of a young and otherwise robust man who has to earn his living, and who would find the expenses entailed by the purchase of voluminous and frequently to be changed dressings, or of any special apparatus, quite beyond his resources, or taking, on the other hand, the case of a weakly patient, in whom the drain of prolonged suppuration would appreciably curtail life, the surgeon may well hesitate before coming to a decision as to which of these methods to adopt.

3. *Dangers and difficulties of nephrectomy.*—In not a few cases death from hæmorrhage alone has been the immediate result of operation. Greig Smith recognised cases where the kidney and surroundings were so much altered that the kidney "could not have been removed from the body by any proceeding claiming to be regarded as surgical." Henry Morris admits cases "in which it was difficult even to dissect the organ away in the post-mortem room," in which it is difficult or impossible to identify where kidney tissue begins and scar tissue ends (if, indeed, they are not inseparably blended), and in which, further, the closure of a urinary sinus is "sometimes impossible"; and other similar opinions could be quoted.

4. *Nature of case for which renal vessel ligation was performed.*—It was upon a case of this nature that the operation which I devised was successfully performed. The patient was a short, thick-set, strong young man, otherwise healthy. Nine months before he came under my care he sustained a rupture of the left kidney, and his very short subcostal space was filled with scar tissue, and a sinus through which pus and urine were freely discharged. I made four attempts to perform nephrectomy but had to abandon the operations partly on account of furious hæmorrhage, partly on account of the impossibility of distinguishing renal from surrounding scar tissue. (Notes of the case are given below.)

5. *No precedent to go upon.*—I have not been able to find any reference to ligature of the renal vessels as an operation to secure a definite surgical result *per se.*

6. *Experimental ligation of renal vessels.*—In various physiological publications and text-books references are made to atrophy of renal epithelium and cessation of urinary secretion as a result of ligature either of the renal arteries or veins. Beddard's experiments on the frog,[2] even allowing for differences between batrachian and mammalian renal blood-supply, lend support to the view that by ligature of the renal vessels the glomeruli of the whole kidney are cut out of the circulation, that complete ligature prevents spontaneous secretion of urine, and that "cutting off the arterial blood-supply of the kidney causes the epithelium of the tubules to degenerate rapidly." De Souza[3] supports Heidenhain's contention "that the amount of urine secreted is directly proportional to the velocity of the blood-flow through the kidneys," and suggests that probably a similar result might be obtained by tying only the renal veins.

7. *Deductions from laboratory experience.*—Reasoning on these lines I concluded that if the renal artery and vein were ligatured complete atrophy of the renal secreting tissue would be insured, and supposing the presence of urine to be the sole hindrance to healing, that if once the secretion of urine within the limits of the abscess ceased, then healing by normal granulation would follow. And this, indeed, was found to be the case; the sinus healed, and I had a letter only a few weeks ago, nearly two years after the operation, in which the patient said he remained quite well, was earning a living, and that the sinus had never reopened.

8. *Significance of blocked ureter.*—In the notes of the case it will be seen that evidence pointed to the conclusion that the ureter had become blocked. It seems obvious that when this is so a renal fistula can never heal spontaneously; it would be quite fortuitous that a blocked ureter (excluding, of course, the case of a removeable, or moveable, calculus) should ever again become patent. It is very seldom advisable to undertake any surgical proceeding with the object of re-establishing patency of a blocked ureter in old suppuration cases; for a successful result, even if achieved, is not likely to remain a permanent one.

9. *The presence of, and final cessation of, urine in the discharge from the sinus.*—At this point I may say that it remains a matter for regret that I did not have some estimate made from time to time during the healing period of the urinary constituents in the discharge from the sinus, for the purpose of comparison with similar analyses made before operation. The presence of urine in the discharge was only too obvious before the operation. After the operation for the first few days the discharge was scanty and smelt faintly of urine. Then, on the fifth day, a large amount of discharge came away in which the smell of urine was not apparent; nor was it ever again present, the discharge appearing as a clear, odourless serous fluid. Healing was complete on the fifty-seventh day after operation. Apparently, then, atrophy of urine-secreting epithelium occurred within five days or so.

10. *Pathology of the cessation.*—It must remain a matter for speculation whether infarction of the whole kidney occurred or whether a more gradual process of atrophy took place. The urine appearing in the discharge for the first few days may well have been a residuum remaining in the various recesses of the abscess.

Having stated the indications for, and the object of, the procedure adopted, one or two points remain to be considered as to (1) the technique, (2) the advantages, and (3) the limitations of the operation.

11. *Technique.*—(*a*) The technique is rather obvious, but remembering the possible existence of accessory or abnormal renal afferent vessels, a search should be made along the aorta to a limited but reasonable extent for these; Zondek found accessory arteries in five out of 15 subjects examined. (*b*) Asepsis can only be assured by avoiding the suppurating area at all costs; this is effected by keeping as far from the kidney as possible and as close to the aorta and vena cava as is safe to apply a ligature. (*c*) Access to the renal pedicle in abdominal nephrectomy is claimed to be safer when made through the outer layer of the meso-colon by reason of less danger to the colic blood-supply; to follow this route, however, would almost certainly open up the

---

[1] A paper read before the Royal Medical and Chirurgical Society on May 28th, 1907.

[2] Journal of Physiology, vol. xxviii., 1902.

[3] Ibid., vol. xxvi., 1900–1901.

septic area, and moreover the colon may be found inseparably united to the kidney. In my case no evil resulted from approaching the renal vessels through the inner mesocolic layer, and this notwithstanding that a search was made for possible renal afferent vessels.

12. *Advantages.*—Properly carried out there is little or no risk from hæmorrhage, shock, or sepsis. As regards (*a*) *hæmorrhage*, this method is in great contrast to any form of piecemeal nephrectomy; (*b*) it is an *aseptic* operation which nephrectomy would certainly not be; and (*c*) subcapsular or piecemeal nephrectomy is at best *a very severe operation*; ligature is not so and shock should not occur; there is inappreciable risk as regards possible damage to the colon or other surrounding organs and serous cavities (septic infection).

13. *Limitations.*—Ligature of the renal vessels may be a very simple proceeding or may be insuperably difficult, and of course there may occur cases where the kidney is so closely adherent to the aorta or the vena cava as to make it impossible to apply a ligature to the vessels. Greig Smith mentions a case where "the aorta and vena cava were so adherent to the kidney that it was found impossible at the autopsy to dissect them apart." I take it that such a condition would be easily recognised through a sufficiently free opening in time to save a blunder. But in the case of the right kidney it might still be possible to ligature the artery by getting at it behind and to the left side of the vena cava, pushing the vessel aside for the purpose of access. Ligature of the artery alone would suffice on laboratory experience to bring about atrophy of the renal epithelium. In the case of the left kidney the renal vein would be accessible and ligature of this alone should bring about a similar result. Von Bergmann mentions a case of Schede's in which an elastic ligature necessarily included a part of the vena cava. The right renal vein is so short (about one inch long) that there would always be danger of opening the septic area in trying to isolate it for purposes of ligature.

Consultations and advice.—An unusual procedure of this sort was naturally not undertaken without first asking the advice of others whose experience would be of great value. First, on several occasions Sir Charles B. Ball very kindly saw the case with me. He quite acquiesced in the view that a further attempt at nephrectomy would not be justifiable, and when at a later date I suggested ligation of the renal vessels he agreed that, though there was no precedent to go upon, it would be worth trying. Finally, I showed the case to him when the sinus had quite healed. To Professor W. H. Thompson, of Trinity College, Dublin, I put the question of the probable result in man of ligature of the renal vessels, and he argued that, from laboratory experience, immediate cessation of urine secretion might be anticipated and then, at an early date, atrophy of the kidney should follow. I had the great advantage of the valuable assistance and wide experience of Dr. W. S. Haughton, surgeon to Steevens's Hospital, Dublin, at two of the attempted nephrectomies, and on each occasion he agreed that the profuse hæmorrhage justified abandonment of the operation. At the final operation (ligature of the renal vessels) I was fortunate in securing the assistance of Dr. R. Atkinson Stoney, senior demonstrator of anatomy, Trinity College, Dublin, and surgeon to the City of Dublin Hospital. My gratitude to these gentlemen is not easily expressed in words.

Conclusion.—In conclusion, though in the first instance this operation was performed when nephrectomy had been attempted and found impossible, I should not hesitate to employ renal vessel ligation in the future as a substitute for nephrectomy where this latter operation promised great difficulty and the likelihood of such severe hæmorrhage as would suffice to turn the scale between life and death in an exhausted patient. Moreover, as a preliminary to a subsequent nephrectomy (a septic operation) an aseptic ligation of the renal vessels would be sound surgery, though I claim that nephrectomy would then be unnecessary, as the ligature would be followed by rapid and permanent cure. Ligature of the renal vessels is surely a great improvement on any form of subcapsular piecemeal nephrectomy or morcellement. The former is a simple, and the latter a very serious, procedure, and both effect the same result.

While quite conscious of the imperfect support that a single successful case affords to a new method, the very rapid, satisfactory, and permanent cure so obtained seems to warrant my bringing the subject before the notice of the Fellows of the society with some confidence that it may be deemed worthy of criticism at least, and possibly of some degree of approval as to its suitability in cases of a similar nature.

Brief history of case.—The patient was aged 19 years. Sept. 14th, 1902: Admitted. Kicked at football previous day. Severe pain in loin. Oct. 2nd: Large abscess opened close to left iliac crest; let out pus and urine. Diagnosis: Rupture of? kidney or ureter.

Jan. 21st, 1903: Extensive empyema evacuated; previous abscess still discharging pus and urine. April 4th: Abscess explored. It extended forward amongst abdominal muscles to near umbilicus, upwards to left pleural cavity, backwards and upwards to left kidney area, downwards into pelvis. Pus in vesical urine. Diagnosed ruptured kidney. June 8th: Sent to Dublin for nephrectomy. 21st: Pyuria; pus and urine discharging from sinus in loin. July 17th: *Operation.*—Attempted nephrectomy; abandoned owing to profuse hæmorrhage; removed five calculi. August 6th: Scar in eighth intercostal space opened spontaneously. Nov. 10th: Skiagraph; shadow of calculus in kidney. 12th: Empyema scar again opened spontaneously, having remained closed six weeks. Dec. 1st: *Operation.*—Attempted nephrectomy; abandoned owing to inadvertently opening peritoneum and inability to define limits of kidney tissue; three calculi removed; very profuse hæmorrhage.

March 6th, 1904: Skiagraphed: further shadow of calculus. 15th: *Operation.*—Two calculi removed; profuse hæmorrhage, therefore gave up attempt at piecemeal nephrectomy; unable to clamp pedicle; collapsed and critical condition for many hours. Sept. 28th: Cathelin's separator: Right ureter, urine acid, clear, no pus or blood, no albumin. Left ureter, urine neutral, opaque, "smoky," pus and blood cells. Nov. 17th: No pus in urine; free discharge of pus and urine from sinus. *Operation.*—Attempted nephrectomy; begin by peeling peritoneum from scar tissue; opened peritoneum inadvertently, at once closed: further separation impossible; removed large calculus from ? pelvis of kidney, having a rounded process of shape and size of ureter, one-third of an inch long; kidney tissue and scar quite inseparable; very severe hæmorrhage. Saline transfusion adopted. 18th: Sudden profuse hæmorrhage threatening life; condition very critical for some hours; hæmorrhage controlled by gauze packing.

Jan. 29th, 1905: Urine (vesical), clear, neutral, no trace of albumin; no pus or blood cells. May 2nd: Urine clear, normal; no shadow of calculus visible: abundant urine and pus from sinus. Cathelin's separator: Right ureter, urine clear, normal; none collected from left ureter. June 13th: *Operation.*—Laparotomy by Lennander's incision. Some difficulty in finding renal vein owing to enlarged lymph glands: vein ligated, then renal artery tied and divided. No accessory afferent vessels found. August 9th: Sinus in loin completely closed. 15th: Discharged quite well.

1907.—Letter to say patient remains quite well. Sinus has never reopened or given any trouble. Until the last operation it had been necessary to apply every day four or more very voluminous dressings; even these were often quite insufficient to take up all the urine and pus, his bed and clothes occasionally becoming soiled. There was not the least tendency to heal, nor did the amount of discharge and urine ever tend to lessen until after the final operation.

TWO CASES OF INFECTION BY THE PARATYPHOID B BACILLUS.

BY EDWARD A. GATES, M.D. LOND., M.R.C.P. LOND.

CASE 1. *Continued fever; four relapses: venous thrombosis; acute bronchitis; cholecystitis; lentigines; agglutination reaction with paratyphoid B bacillus.*—The patient was a woman, aged 54 years. After a week's malaise she took to her bed on Nov. 28th, 1906, and remained there until March 19th, 1907. The initial symptoms were intense headache, slight epistaxis, vomiting, and fever. There were a few roseolous spots on the chest and abdomen; the tongue was furred; the spleen was enlarged, descending two fingers' breadth below the costal margin, and the liver one finger's breadth. The right kidney was freely palpable. Constipation was present. The urine gave a well-marked diazo reaction and contained a trace of albumin with, microscopically, many white cells. On Dec. 3rd the blood serum was sent to the laboratory of the hospital of Santa Maria Nuova to be tested for the reaction with the typhoid bacillus. The report was returned that the reaction was positive. The other features of the case being so strongly in favour of this diagnosis the exact details of the reaction were not demanded until a much later date, when it was found that the test had only been made with a dilution of 1 in 40, and that it was at the end of three hours that agglutination was observed to have taken place both macroscopically and microscopically. The temperature gradually mounted, reaching its maximum (104·4° F.) on Dec. 5th, the pulse-rate varying between 88 and 104. After this the temperature declined gradually with daily oscillations of about 2°, the maximum on Dec. 20th being 100·6°. After this it gradually rose again and reached 103·2° on Jan. 8th, 1907, and continued irregularly raised until the 30th, when the patient had a severe rigor. Immediately after this for two or three days rhonchi were heard all over both lungs.

Up to this time, though the fever continued, the patient appeared to be making satisfactory progress, except for the fact that on Jan. 24th she had had pain in the left groin and inner side of the left thigh, with tenderness over the left femoral vein. This, however, subsided in a couple of days and was not accompanied by any œdema. There was now no headache, the mind was quite clear, the patient was cheerful, the bowels acted well to daily enemata, the urine was normal except for a fine trace of albumin, and food was well taken, consisting of one and a half litres of milk and two eggs daily. During the first fortnight of February the temperature oscillated between 98° and 100° but on the 14th it began again to ascend, reaching 103·6°, with a slight shivering attack on the 20th. The general condition remained excellent. There was no new symptom to account for the rise of temperature. On the 26th a few fresh rose spots appeared on the abdomen. During February the patient and her nurses observed that she had become extensively freckled on the face, trunk, and limbs, the spots on the last being stains as large as a shilling-piece. The patient declared that she had never before in her life had any freckling of the skin.

On Feb. 27th blood serum was taken and sent to the pathological laboratory of the University of Florence for examination of its reaction on typhoid and paratyphoid bacilli. The examinations were made by Dr. Menini, assistant to Professor Lustig, under Professor Lustig's personal supervision. The report was returned: "Agglutination test executed March 2nd, 1907, with the blood serum of Mrs. ——. In the dilution of 1 in 100 at the temperature of the room: Negative for the bacillus of typhoid (origin of culture, Berlin). Negative for the paratyphoid bacillus A (laboratory culture). Positive (in about half an hour) for the paratyphoid bacillus B (laboratory culture)."

From Feb. 25th the temperature had been slowly falling, and on March 2nd and 3rd had not risen above 99°. On March 3rd the patient began to have pain round the upper part of the abdomen. This pain was very severe during the night. On the following day the temperature rose with a slight shivering attack to 101·8°. There was great tenderness in the right hypochondrium but the outline of the gall-bladder could be mapped out, its lower edge reaching to the level of the umbilicus. There were no jaundice and no bile in the urine. The temperature was normal on the 5th and remained so for ten days. The tenderness soon subsided, but the enlargement of the gall-bladder had not wholly disappeared even on the departure of the patient from Florence in the middle of May. On March 13th fish was allowed and on the 15th minced chicken. On the 16th the temperature began to rise slightly but never above 100° and on the 28th it was normal morning and evening. On the 19th the patient was up for an hour, having been continuously in bed until this date from the 26th of the preceding November. At the beginning of April the temperature was again irregularly, though but slightly, raised, reaching 100·2° on the 8th and 9th, and did not become regularly normal until the 19th. On the 8th and 9th there was some return of the tenderness over the gall-bladder and the patient was kept in bed for three days. After she began to walk the left leg and thigh swelled to some extent, with pitting over the tibia. The swelling was not great and had already become less when the patient left Florence in the middle of May.

CASE 2. *Catarrhal jaundice; slight fever; agglutination reaction with paratyphoid B bacillus.*—The patient, aged 21 years, who was the daughter of Case 1 and lived in the same apartment, was taken ill with a "bilious attack" on Dec. 7th, 1906, and developed jaundice with symptoms of obstruction of the outflow of bile. There was slight elevation of temperature, but never above 100° F. The symptoms rapidly subsided except the slight rise of temperature, which persisted for a week and probably longer, as the patient, feeling quite well, was allowed up and the temperature was no longer taken. During the rest of the winter and spring she was in the best of health. After the blood serum of the mother (Case 1) had given such a decided reaction with the paratyphoid bacillus that of the daughter was also sent for examination at the pathological laboratory of the University and submitted by Dr. Menini to the same tests on March 6th with identical results—that is, the reaction was negative with typhoid and paratyphoid A bacilli, but positive in a dilution of 1 in 100 in half an hour with paratyphoid B bacilli.

Florence.

A CASE OF RECURRENT PNEUMOTHORAX.

BY JOHN CARUTHERS SALE, M.R.C.S. ENG., L.R.C.P. LOND.

ON June 3rd, 1906, I was called to see the patient, a well-developed woman, aged 21 years, by occupation a draper's assistant, who complained of pain in the right side of the chest and shortness of breath. The history of her illness was as follows. In July, 1901, she had a cough and began to spit up a little blood. She had never previously had a cough except when suffering from an ordinary catarrh. She had whooping-cough in childhood but had never had pleurisy or pneumonia. There was no history of tubercle in the family but her mother suffers from well-marked acromegaly. In August, 1901, about three weeks after she commenced to spit blood, whilst brushing her hair in the morning, she suddenly felt a sharp pain in the right side, which was worse on lifting the right arm. She also had a cough, was short of breath, and could not lie on her right side. When the pain came on the spitting of blood ceased. She was seen by a medical man who diagnosed pneumothorax. She was in bed for a month and resumed work at the shop in three months, feeling quite well. She was told at the time that she had not got consumption. In April, 1902, she had a similar attack which was not so severe. She stayed at home for a week but did not go to bed and did not consult a medical man. In August, 1902, she was again taken with shortness of breath and a dry cough but on this occasion had no pain. In each of the years 1903 and 1904 she had two attacks. On three out of the four attacks she was seen by a medical man who told her that she had pneumothorax but that he could discover no signs of consumption. In February, 1905, whilst staying at a distance she had another attack and was in bed for three weeks. The medical man who attended her there told her that it was another attack of pneumothorax and that her lungs were not diseased.

In April, 1906, she had a further attack but not a severe one. It came on just as she came downstairs. She remained at home for a week but did not consult anyone. From then she remained in good health until the day on which I saw her. On the night of June 2nd, 1906, she went to bed at 12 o'clock. At 1 A.M. she awoke with pain in the right side and shortness of breath. When I saw her at 6 A.M. her condition was as follows. She was lying on her back; her face was rather flushed; her respirations were 32 per minute; her temperature was 99° F. and her pulse-rate was 108. She had a slight dry cough. The right side of the chest moved badly but was not immobile. Vocal vibrations were absent over the whole of the right chest. There was hyper-resonance all over the right side of the chest; there was no dulness at the base. On auscultation amphoric breathing was heard over the whole of the right chest; the vocal resonance was faint; there was no metallic tinkling; the "bell sound" could be obtained. The heart was not displaced. She remained in bed for three weeks, at the end of which time all the symptoms had subsided. The cough disappeared in a week and at no time was there any expectoration. In two months the patient returned to her employment and at that time on examination her chest appeared to be quite natural. The percussion note and respiratory murmur were equal on both sides, the chest expanded well, and there were no added sounds. Up to the present time—April, 1907—she has remained in good health and runs up and down stairs without any discomfort. She has had no further cough and her lungs, on examination, appear to be quite healthy.

According to the patient's account she has had ten attacks of pneumothorax. I think her account can be relied upon, for, so far as I have been able to ascertain, she can invariably diagnose her own condition with certainty. She knows the onset accurately. There is little shortness of breath as a rule, but there are usually some pain and a dry irritating cough which soon passes off. Between the attacks she has no cough or sputum and she has never had any hæmoptysis since the first attack of pneumothorax. In each attack, so far as I can ascertain, there has been a complete pneumothorax with no sign of fluid at any time during the progress of the case, yet sometimes she is very little affected, at others much distressed. Possibly the size of the opening may account for this variation, a small opening causing a ore gradual and therefore less distressing development of mptoms.

Most of the reported cases of recurrent pneumothorax an apparently healthy person have eventually turned out be tuberculous in origin. The hæmoptysis immediately receding the initial attack seems to point to that theory this case, but though it is now nearly six years ince the first attack no signs of pulmonary tuberculosis ave developed and the patient is becoming stouter and more obust. The largest number of attacks of pneumothorax n one person that I have been able to find is four in a case eported by Dr. D H. Gabb in the *British Medical Journal* of July 28th, 1888, and reprinted by Dr. Byrom Bramwell in vol. iv. of "*Clinical Studies.*" In this case there was no sign of pulmonary tuberculosis.

Since the above was written this patient has had another attack of pneumothorax, making 11 in all. The attack came on as she was walking in the street and was not attended by much distress. She insisted on going back to business in three weeks from the onset before the air was entirely absorbed and is apparently none the worse for so doing.

Skegness.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DISLOCATION OF THE CLAVICLE DUE TO PROMINENT CERVICAL RIB.

BY F. D. BENNETT, M.R.C.S. ENG., L.R.C.P. LOND.

THE following case may be of interest as I am unable to find a similar one recorded.

A boy, aged 14 years, of normal physique came before me for examination and presented the following condition. On the left side was a prominent cervical rib projecting to, and touching, the clavicle about the centre. At first sight it presented the appearance of an old fracture of the clavicle with considerable callus around. During the passage of the clavicle over the end of the rib in elevation or lowering of the shoulder the sternal end of the clavicle to admit of its passage over the rib was dislocated forwards and returned to its normal position immediately the bone had passed above or below the rib. Owing to the difficulty of photographing the part some x ray photographs do not show the condition as I should have wished. The lad suffered no inconvenience and was unaware of any abnormal condition.

Weymouth-street, W.

A CASE OF OLD-STANDING DIAPHRAGMATIC HERNIA DISCOVERED POST MORTEM.

BY PENROSE WILLIAMS, M.R.C.S. ENG., L.R.C.P. LOND.

A MAN, aged 77 years, was admitted to the Bridgwater Hospital under my care for hæmatemesis with a history of difficulty in swallowing and wasting of several months' duration; he died rather suddenly within 40 hours.

At the necropsy the left side of the chest from the diaphragm to two inches above the horizontal nipple line was found to be occupied by an oval cystic swelling which proved to be the stomach. Behind it was a coil of intestine consisting of the whole of the transverse colon, part of the ascending colon, and the great omentum. The heart was displaced to the right, being entirely on that side of the middle line, and completely covered by portions of the right and left lungs. The right lung occupied a normal position but the left lung was pushed upwards and to the right and was shaped to accommodate the stomach. In the diaphragm to the left of the middle line and posteriorly was a horse-shoe shaped opening, having its convexity forwards and bounded posteriorly by the chest-wall; the margin was smooth, rounded, and thickened, and terminated behind in two "crura," one overlapping the other; the opening admitted four fingers on the flat, or the whole hand cone-shaped. The omentum was firmly adherent to the margin of the opening, the upper surface of the diaphragm, the chest-wall, and the left lung, and the fundus of the stomach was adherent to the left lung. The œsophagus apparently passed through the diaphragm in its usual position, the stomach thence passing abruptly back again into the chest through the accessory opening; the pylorus lay just below this opening; the other abdominal contents were normal except that the transverse colon passed in a straight line from the cæcum to the diaphragmatic opening, and the descending colon, which was empty and contracted to the size of a man's forefinger, passed in a straight line to the sigmoid flexure.

The dense adhesions, the characters of the opening, and the shape of the left lung, which was not merely displaced by pressure but had apparently grown into a hollow shell-like covering for the stomach, suggest that the hernia was not recent and not traumatic, and this, together with the unusual extent of the displacement, seems worth recording.

Bridgwater.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Lantern Demonstrations.—Colour Vision.—Syphilitic Affections of the Eye.—Rupture of the Pectinate Ligament.—After-Cataract.—Perinaud's Conjunctivitis.—Telangiectasis of Retinal Vessels.—Exhibition of Specimens.

A MEETING of this society was held on May 25th, Mr. J. PRIESTLEY SMITH, the President, being in the chair.

Mr. GEORGE COATS gave a lantern demonstration on the Pathology of Rupture of Descemet's Membrane. This was first discovered microscopically by Becker in 1875. Mr. Coats had found these ruptures in 12 of 13 cases of buphthalmos, and in two of eight cases of glioma with increased tension. They were absent in four cases of high myopia. The ruptured ends were sometimes found to be flat, and sometimes curled up, but the rupture itself was almost always covered with endothelium. At times extensive detachment of the membrane was found. Experimentally he found that the globe would give way before the membrane would rupture, but if the membrane was first scratched many features of the rupture could be reproduced.

Dr. F. W. EDRIDGE-GREEN gave an account of his observations with Lord Rayleigh's Colour-mixing Apparatus and showed a table which brought out the fact that there were extraordinary differences in the way in which people were able to match the colours. This was not due to any physical condition present but could be readily explained physiologically in accordance with his (Dr. Edridge-Green's) theory of colour vision.

Dr. ALEXANDER BRUCE gave a lucid lantern demonstration of the Third Nerve Nucleus and its surrounding parts

Mr. SYDNEY STEPHENSON described the present position of the Spirochæta Pallida in Relation to Syphilitic Affections of the Eye. After briefly reviewing the evidence in favour of the spirochæta pallida being the specific element of syphilis he described the special researches which had been made on the eyes of man and the lower animals. In congenital syphilis the organism had been found by Stock, Peters, Römer, Bab, and himself. He detailed the experiments of other observers who had produced interstitial keratitis in the eyes of monkeys and rabbits with syphilitic material from man and had found spirochætæ in the lesions thereby produced. As regards clinical syphilis of the eye, the organism had been found by himself and other observers, and he expressed his belief that the presence of Schaudinn's organism was the strongest possible proof of the syphilitic nature of any given disease of the eye or of any of its appendages.

Dr. LESLIE BUCHANAN showed a series of lantern slides of Preparations of Eyes of Invertebrates with the object of indicating that from the anatomical structure a certain amount of information can be obtained as to the degree of functional activity of which the organ is capable. The preparations included sections of the eye of the octopus, the clam, the spider, the caterpillar, the house fly, the bee, and the snail. Sections of the eye of the Australian mole and of the leech were shown to illustrate the fact that loss of functional activity leads to anatomical degeneration.

Dr. BUCHANAN also demonstrated a case of Rupture of

Up to this time, though the fever continued, the patient appeared to be making satisfactory progress, except for the fact that on Jan. 24th she had had pain in the left groin and inner side of the left thigh, with tenderness over the left femoral vein. This, however, subsided in a couple of days and was not accompanied by any œdema. There was now no headache, the mind was quite clear, the patient was cheerful, the bowels acted well to daily enemata, the urine was normal except for a fine trace of albumin, and food was well taken, consisting of one and a half litres of milk and two eggs daily. During the first fortnight of February the temperature oscillated between 98° and 100° but on the 14th it began again to ascend, reaching 103·6°, with a slight shivering attack on the 20th. The general condition remained excellent. There was no new symptom to account for the rise of temperature. On the 26th a few fresh rose spots appeared on the abdomen. During February the patient and her nurses observed that she had become extensively freckled on the face, trunk, and limbs, the spots on the last being stains as large as a shilling-piece. The patient declared that she had never before in her life had any freckling of the skin.

On Feb. 27th blood serum was taken and sent to the pathological laboratory of the University of Florence for examination of its reaction on typhoid and paratyphoid bacilli. The examinations were made by Dr. Menini, assistant to Professor Lustig, under Professor Lustig's personal supervision. The report was returned: "Agglutination test executed March 2nd, 1907, with the blood serum of Mrs. ——. In the dilution of 1 in 100 at the temperature of the room: Negative for the bacillus of typhoid (origin of culture, Berlin). Negative for the paratyphoid bacillus A (laboratory culture). Positive (in about half an hour) for the paratyphoid bacillus B (laboratory culture)."

From Feb. 25th the temperature had been slowly falling, and on March 2nd and 3rd had not risen above 99°. On March 3rd the patient began to have pain round the upper part of the abdomen. This pain was very severe during the night. On the following day the temperature rose with a slight shivering attack to 101·8°. There was great tenderness in the right hypochondrium but the outline of the gall-bladder could be mapped out, its lower edge reaching to the level of the umbilicus. There were no jaundice and no bile in the urine. The temperature was normal on the 5th and remained so for ten days. The tenderness soon subsided, but the enlargement of the gall-bladder had not wholly disappeared even on the departure of the patient from Florence in the middle of May. On March 13th fish was allowed and on the 15th minced chicken. On the 16th the temperature began to rise slightly but never above 100° and on the 28th it was normal morning and evening. On the 19th the patient was up for an hour, having been continuously in bed until this date from the 26th of the preceding November. At the beginning of April the temperature was again irregularly, though but slightly, raised, reaching 100·2° on the 8th and 9th, and did not become regularly normal until the 19th. On the 8th and 9th there was some return of the tenderness over the gall-bladder and the patient was kept in bed for three days. After she began to walk the left leg and thigh swelled to some extent, with pitting over the tibia. The swelling was not great and had already become less when the patient left Florence in the middle of May.

Case 2. *Catarrhal jaundice; slight fever; agglutination reaction with paratyphoid B bacillus.*—The patient, aged 21 years, who was the daughter of Case 1 and lived in the same apartment, was taken ill with a "bilious attack" on Dec. 7th, 1906, and developed jaundice with symptoms of obstruction of the outflow of bile. There was slight elevation of temperature, but never above 100° F. The symptoms rapidly subsided except the slight rise of temperature, which persisted for a week and probably longer, as the patient, feeling quite well, was allowed up and the temperature was no longer taken. During the rest of the winter and spring she was in the best of health. After the blood serum of the mother (Case 1) had given such a decided reaction with the paratyphoid bacillus that of the daughter was also sent for examination at the pathological laboratory of the University and submitted by Dr. Menini to the same tests on March 6th with identical results—that is, the reaction was negative with typhoid and paratyphoid A bacilli, but positive in a dilution of 1 in 100 in half an hour with paratyphoid B bacilli.

Florence.

A CASE OF RECURRENT PNEUMOTHORAX.

By JOHN CARUTHERS SALE, M.R.C.S. Eng.,
L.R.C.P. Lond.

On June 3rd, 1906, I was called to see the patient, a well-developed woman, aged 21 years, by occupation a draper's assistant, who complained of pain in the right side of the chest and shortness of breath. The history of her illness was as follows. In July, 1901, she had a cough and began to spit up a little blood. She had never previously had a cough except when suffering from an ordinary catarrh. She had whooping-cough in childhood but had never had pleurisy or pneumonia. There was no history of tubercle in the family but her mother suffers from well-marked acromegaly. In August, 1901, about three weeks after she commenced to spit blood, whilst brushing her hair in the morning, she suddenly felt a sharp pain in the right side, which was worse on lifting the right arm. She also had a cough, was short of breath, and could not lie on her right side. When the pain came on the spitting of blood ceased. She was seen by a medical man who diagnosed pneumothorax. She was in bed for a month and resumed work at the shop in three months, feeling quite well. She was told at the time that she had not got consumption. In April, 1902, she had a similar attack which was not so severe. She stayed at home for a week but did not go to bed and did not consult a medical man. In August, 1902, she was again taken with shortness of breath and a dry cough but on this occasion had no pain. In each of the years 1903 and 1904 she had two attacks. On three out of the four attacks she was seen by a medical man who told her that she had pneumothorax but that he could discover no signs of consumption. In February, 1905, whilst staying at a distance she had another attack and was in bed for three weeks. The medical man who attended her there told her that it was another attack of pneumothorax and that her lungs were not diseased.

In April, 1906, she had a further attack but not a severe one. It came on just as she came downstairs. She remained at home for a week but did not consult anyone. From then she remained in good health until the day on which I saw her. On the night of June 2nd, 1906, she went to bed at 12 o'clock. At 1 A.M. she awoke with pain in the right side and shortness of breath. When I saw her at 6 A.M. her condition was as follows. She was lying on her back; her face was rather flushed; her respirations were 32 per minute; her temperature was 99° F. and her pulse-rate was 108. She had a slight dry cough. The right side of the chest moved badly but was not immobile. Vocal vibrations were absent over the whole of the right chest. There was hyperresonance all over the right side of the chest; there was no dulness at the base. On auscultation amphoric breathing was heard over the whole of the right chest; the vocal resonance was faint; there was no metallic tinkling; the "bell sound" could be obtained. The heart was not displaced. She remained in bed for three weeks, at the end of which time all the symptoms had subsided. The cough disappeared in a week and at no time was there any expectoration. In two months the patient returned to her employment and at that time on examination her chest appeared to be quite natural. The percussion note and respiratory murmur were equal on both sides, the chest expanded well, and there were no added sounds. Up to the present time—April, 1907—she has remained in good health and runs up and down stairs without any discomfort. She has had no further cough and her lungs, on examination, appear to be quite healthy.

According to the patient's account she has had ten attacks of pneumothorax. I think her account can be relied upon, for, so far as I have been able to ascertain, she can invariably diagnose her own condition with certainty. She knows the onset accurately. There is little shortness of breath as a rule, but there are usually some pain and a dry irritating cough which soon passes off. Between the attacks she has no cough or sputum and she has never had any hæmoptysis since the first attack of pneumothorax. In each attack, so far as I can ascertain, there has been a complete pneumothorax with no sign of fluid at any time during the progress of the case, yet sometimes she is very little affected, at others much distressed. Possibly the size of the opening may account for this variation, a small opening causing a of broncho-pneumonia and 24 of lobar; of the latter only one was as young as two years of age. In the post-mortem records of lobar pneumonia during 1905 of 50 cases only seven were in children, one in the first year, two in the second, and one in the third year. Similar discrepancies existed with regard to the mortality of lobar pneumonia, considered by most writers not to amount to more than from 1 to 5 per cent., while others put it as high as 25 per cent. or even more in the first two years of life. Very different estimates had been given of the relative frequency of the two forms of pneumonia, but lobar pneumonia had been generally admitted to be less frequent by those who had seen the largest number of cases. The discrepancies were due to many causes, such as varying conditions of admission into the hospitals, the influence of epidemics, or errors of diagnosis, &c. Some relied upon a crisis as a sign of lobar pneumonia but in the first two years half the cases recovered without this sign. Again, extensive consolidation might be produced by broncho-pneumonia and lobar and broncho-pneumonia might co-exist. Bacteriology was of little help. The conclusions seemed to be that great differences in frequency might occur in different places and at different times, broncho-pneumonia was uncommon after three years of age, and lobar pneumonia was more frequent in infants than used to be thought, possibly it varied more with epidemic prevalence than broncho-pneumonia. The observations of Nobecourt and Voisin were mentioned; they found that when nervous symptoms appeared the cerebro-spinal fluid was unusually abundant, and in two cases it was turbid and contained polymorphonuclear cells and pneumococci. Dr. Taylor concluded by alluding to treatment and to the probable value of a bacteriological method when such a treatment was discovered.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A laboratory meeting of this society was held on May 8th, Dr. A. Hill Griffith being in the chair.—The following specimens, &c., were shown:—Dr. J. Cameron: Microscopical specimens illustrating the Peripheral Development of Nerve Fibres.—Dr. D. E. Core: (*a*) Microscopical specimens of Blood from a case of acute Lymphatic Leucocythæmia and (*b*) Verminous Bronchitis in a hedgehog.—Dr. E. N. Cunliffe: Blood films illustrating (*a*) a case of Splenic Anæmia of unusual type and (*b*) Lymphatic Leucocythæmia.—Dr. Hill Griffith: Pathological Eye specimens.—Dr. A. E. Johnson: Method of Sterilising Animal Ligatures.—Dr. Arnold W. W. Lea: Lantern demonstration illustrating various Micro-organisms occurring in Puerperal Septic Metritis.—Professor J. Lorrain Smith: An unusual case of Cirrhosis of the Liver.—Dr. G. E. Loveday: Wright's Method of Counting the Blood Corpuscles.—Dr. W. Mair: Hydrocephalic Brain in a case of Tuberculous Tumour of the Cerebellum.—Dr. C. H. Melland: Granular Degeneration of the Red Corpuscles in Lead Poisoning and other conditions.—Dr. H. H. McNabb: Methods of Mounting Eye Specimens, with examples.—Dr. J. G. McNaughton: (*a*) Congenital Absence of One Kidney, and (*b*) Cerebellar Abscess.—Dr. D. Orr and Dr. R. G. Rows: Sections showing Invasion of the Spinal Cord by Micro-organisms *viâ* the Spinal Nerve Roots.—Dr. A. Sellers and Dr. Sidebotham: The Bacteriology of Cerebro-spinal Meningitis.—Dr. C. Powell White: (*a*) Apparatus for Regulating the Temperature of a Warm Stage for the Microscope, and (*b*) Anisotropic Globules in Tumours.—Dr. R. B. Wild and Dr. C. S. O'Neill: An Improved Method for the Physiological Standardisation of the Digitalis Group.—Mr. R. H. Wolstenholme: Stomach of a Horse with Larvæ of the Gastrophilus equi *in situ*.

THE ROYAL BRADFORD EYE AND EAR HOSPITAL.—The Bradford Eye and Ear Hospital, which was founded in 1857 by the late Dr. Edward Bronner and will this year celebrate its jubilee, is in future, by the permission of the King, to be called "The Royal Bradford Eye and Ear Hospital." It is now one of the largest special hospitals in the kingdom and contains 45 beds During last year 7270 new patients were treated, 1091 in-patients were admitted, and 1034 major operations were performed, including 160 extractions of senile cataract. Since the foundation of the hospital 153,848 cases have been treated and 20,791 major operations have been performed. The present hospital is too small for the large number of in- and out-patients and the committee is considering the question of building a large separate out-patient department.

Reviews and Notices of Books.

Geschichte der Medizin (*History of Medicine*). Von Dr. MAX NEUBURGER, ä.o. Professor für Geschichte der Medizin an der k.k. Universität in Wien, &c. I. Band. Stuttgart: Ferdinand Enke. 1906. Pp. 403. Price M.9, or 9*s*.

HOWEVER distinct the various sciences may appear they are yet only branches of human knowledge and are largely influenced by each other and by current metaphysical and even ethical opinions. The science and art of medicine are thus to a great extent dependent on a variety of surrounding circumstances, and it has been the aim of the author in the work before us to trace the gradual development of the healing art in connexion with that of knowledge in general and to point out the traces which are to be found at different epochs of the moulding of its tenets in accordance with the philosophy of the day. In the earliest times, as represented by the civilisations of Babylon and Egypt, superstition of all kinds was rampant. Gods and demons were believed to interfere directly with all the affairs of human life, and charms and incantations were an important part of medical procedure. Yet as knowledge grew and the mechanical and physical sciences were evolved medicine tended to develop on scientific lines; a large number of medicinal substances were recognised and surgery reached a considerable degree of technical efficiency. In Greece where superstition was early thrown off and free speculation pushed into all regions of the unknown rational medical methods were soon elaborated, and beside the spiritualistic and occult rites of the Orphics and other *mystics*, schools of medicine came into existence in association with various temples and priestly orders, at which a surprising degree of real knowledge appears to have existed. About the period of the highest intellectual development of the Greek race, in the fifth century before Christ, arose the great master of medicine—Hippocrates—whose name is still synonymous with the spirit of the true physician. Discarding all reliance upon occult influences and regarding all diseases as equally due to natural causes—*none* more directly sent from heaven than another—he pointed out the sure way to advance the knowledge of medicine, by careful observation of clinical phenomena, and at the same time laid down those canons of professional conduct which are still regarded as binding on the physician in his relations with the sick. Just as Socrates represents the application of the inquiring Greek spirit to the philosophy of ordinary life, so Hippocrates personifies the scientific spirit in medicine, the refusal to be bound by preconceived theories and the recognition of the good of the individual patient as the object at which to aim. After his death, with the decadence of Greek intellectual life, a large number of different sects arose, each insisting on some one aspect of the problem of disease and neglecting that sane appreciation of the whole subject which alone enables us to see order among a chaos of details, instead of distorting the facts to fit a fine-spun metaphysical theory. With the conquests of Alexander and the spread of the influence of Rome Greek methods of thought were distributed throughout the world and brought under their influence Asiatic and African races as well as those of Europe. The silver age of Greek literature at the court of the Ptolemies corresponded with a development of the arts and sciences, and the practical side of medicine was advanced by such teachers as Herophilus and Erasistratus. Anatomy and surgery were brought to a high pitch of development, whereas little of importance was added to the field of pathology. In Rome medical knowledge owed everything to imported Greek culture; no original writer of any importance arose among the

the Pectinate Ligament. A man was struck on the left eye by a broom handle at the end of June, 1906. Amongst other injuries to the eye there was what appeared to be a large coloboma of the iris in a downward and inward direction accompanied by high tension and loss of vision. The case was considered to be one of rupture of the pectinate ligament with displacement of the iris and ciliary body backwards along the sclera. As the eye continued to be painful it was excised in January, 1907, when, after histological examination, the diagnosis was proved to be correct. Microscopic preparations were shown.

Dr. ANGUS MCGILLIVRAY read a paper on the Treatment of After-Cataract. To obviate the dragging on the ciliary body and the risk of cyclitis he divided the capsule diagonally from above downwards and inwards by very short and steady sawing movements by means of a specially designed cutting needle. Since adopting this sawing method of dividing opaque capsule after cataract extraction little or no trouble had been experienced; so little, in fact, that he did not now hesitate to divide an opaque capsule when the vision was, from this cause, below $\frac{6}{12}$ths.

Dr. MCGILLIVRAY also showed a very convenient Storage Battery for ophthalmic use.

Dr. ARTHUR H. H. SINCLAIR and Dr. THEODORE SHENNAN described a case of Perinaud's Conjunctivitis in a man, aged 61 years, who was a painter's labourer. The left eye became affected during the third week in July, 1906. About three weeks later the surrounding lymphatic glands became enlarged. The patient was under observation for four months and had not completely recovered when he ceased his attendance and could not be further traced. Dr. Shennan described carefully the histological and bacteriological condition found. Two varieties of staphylococci were the organisms discovered.

Dr. W. B. INGLIS POLLOCK described a case of Telangiectasis of the Retinal Capillaries and Venous Radicles. The condition followed on fracture of the left side of the skull, due to a heavy weight falling upon the head. He showed an ophthalmoscopic drawing of the fundus.

Numerous card specimens were shown.

Dr. SINCLAIR showed: (1) A Collapsible Apparatus for Testing the Field of Vision; (2) the charts from a case of Glaucoma, showing remarkable restriction of the fields of vision in both eyes; and (3) a case of Retinitis Punctata Albescens.

Dr. BRUCE showed two cases of Intracranial Neoplasms.

Dr. ROBERT A. FLEMING gave a microscopical demonstration of an Optic Neuritis in Relation to Intracranial Tumours, with special reference to the changes in the neuroglia cells.

Dr. E. BRAMWELL exhibited: (1) A Brain showing Occipital Abscess from a case in which epileptic fits were preceded by visual auræ and in which hemiachromatopsia developed; and (2) a case of Ocular Palsy, with Congenital Absence of Cranial Nerve Nuclei.

Mr. G. A. BERRY showed several cases. He exhibited a Loupe for the Use of Myopes and Test Objects for Illiterates.

Dr. G. MACKAY exhibited some Unusual Clinical Cases and Coloured Drawings.

Dr. W. G. SYM showed a case of Complete Congenital Anophthalmos and other cases.

Dr. J. V. PATERSON showed a case of Tubercle of the Conjunctiva and a well-marked case of Reticular Keratitis.

Dr. A. MAITLAND RAMSAY exhibited on Opaque Projector for Teaching Purposes and some Pathological Specimens.

Lieutenant-Colonel H. HERBERT, I.M.S., gave a lantern demonstration of the Sinuous Lid Border as a sign of Trachoma.

EPIDEMIOLOGICAL SOCIETY.—At a meeting of this society on May 31st Dr. Axel Holst, Professor of Hygiene of the University of Christiania and Foreign Secretary for Norway, said that the symptoms of ship beri-beri consisted in weakness and a pronounced dropsy of the lower limbs, extending often to other parts of the body. There were also shortness of breath and other symptoms of a weak heart, causing not infrequently sudden death from acute cardiac paralysis. Considering that neuritis was the essential symptom of the beri-beri of tropical countries and Japan it seemed rather doubtful whether ship beri-beri was identical with it. Further, the great majority of patients suffering from the ordinary—i.e., dropsical—ship disease recovered as soon as they were able to change their diet, which was not the case with the disease of the tropics and Japan. Proceeding to the question what defects of the food might be able to cause ship beri-beri, he said that the Norwegian sailors nearly always used on long voyages soft bread of an inferior quality, to a large extent raw and baked without yeast. The sailors on long voyages were mostly compelled to use dried potatoes instead of fresh ones, because the latter did not easily keep in the tropics. Dried potatoes, however, as well as dried green vegetables, during the North American War of Rebellion proved to be of no value as a remedy against scurvy. At the same time they were, in course of their preparation, usually boiled in water containing some hydrochloric acid before being dried. Norwegian sailors ate very freely of tinned meat that had been strongly heated. Such meat might, however, have lost some of its anti-scorbutic power, or it might even be able to produce scurvy, because strongly heated milk seemed to be able to produce infantile scurvy. Dr. Holst showed from his experiments on pigeons that bread of wheat-flour—i.e., the flour ordinarily used by Norwegian sailors in tropical waters—was much more injurious than rye bread. The experiments further showed that the effect of wheat bread prepared with baking powder similar to the poor quality bread used by the Norwegian sailors on long voyages was more injurious than that of bread baked with yeast. The latter difference could not be ascribed to any poisonous effect of the baking powder, because the rye-bread, prepared in the same way, did not produce the same result. From experiments on chickens it seemed evident that beef was able to produce polyneuritis in chickens, even when boiled at a lower temperature than the 120° C. usually reached in the manufacture of tinned meat, and the polyneuritis must be considered as due to a special injurious effect of the nutriments applied. The beef had always recently been boiled. The effect of the strongly heated beef could only be ascribed to a decomposition of one or more constituents of the beef produced by the high temperature or high steam pressure used in the boiling. The experiments were of interest on account of the additional light which they threw upon the deterioration of food by strong heating. That point was important not only in regard to the nutritive value of tinned food but also in reference to the steam boiling of different articles of food used in modern hospitals, because the latter was often carried out at a temperature of about 110° C., which temperature when applied for half an hour produced alteration of the nutritive elements of beef.—Dr. Axel Holst and Dr. Theodor Frölich contributed a paper on the Etiology of Scurvy, showing that a diet consisting of grains, groats, and bread, regularly produced in guinea-pigs a disease that was macro- as well as micro-scopically identical with scurvy. On the other hand, this disease did not appear when the animals were fed on fresh cabbage or boiled fresh potatoes only. Again, it was produced by an exclusive feeding on dried potatoes. It was further found that the disease was influenced favourably by the nutriments which were known in human pathology as "anti-scorbutica," but that cabbage lost some, but not all, of its anti-scorbutic power when boiled for half an hour at 110° C. Examples were given showing that the same or similar nutriments that produced the disease in guinea-pigs had also produced scurvy in man. On the other hand, they had not hitherto been able to produce the malady known as ship beri-beri. It was true that they had repeatedly seen, after an addition of anti-scorbutic nutriments to grains or bread, the occurrence of a disease with œdema, but without hæmorrhages. The œdema, however, did not occur regularly, nor was it accompanied by neuritis. They were, therefore, at present not able to form any distinct idea as to the causation of ship beri-beri. The same applied to the question as to the precise causes of the influence of certain diets.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on May 17th at which the Wightman lecture was delivered by Dr. Frederick Taylor on Pneumonia in Children. He discussed the relative frequency of lobar and broncho-pneumonia in children. He mentioned that till the test of inflation was systematically employed collapse was confused with broncho-pneumonia; when this was demonstrated it was considered that the previous error had led to an under-estimation of the importance of lobar pneumonia in children. This had led to many papers on the subject. Clive Riviere stated that the greatest incidence of lobar pneumonia was in the second year of life and after that in the third year. Vere Pearson also found croupous pneumonia more common in infancy than in any other age of childhood. Bertram Abrahams regarded it as a common affection from the age of two years upwards. Ashby considered it more common after the first two years. In Guy's Hospital Dr. Taylor found during one year 35 cases as "occupied"; and of the males 1,399,969 were occupied and 273,916 unoccupied. Further, as regards occupation, the compilers divide each of the sexes into five groups, comprising "orders" or trades arranged according to the importance of the number of persons employed therein. Of the occupied males, 781,798, or 55·8 per cent., of them were employed in the conveyance of men, goods, and messages, in building, in providing food, tobacco, drink, and lodging, in commercial life, and as general or undefined workers and dealers; while 367,545 others of them, or 26·3 per cent., were employed in the following "orders"—viz.: (1) metals, machines, implements, and conveyances; (2) dress; (3) professional; (4) paper, prints, books, and stationery; and (5) wood, furniture, fittings, and decorations. These two groups account for 1,149,343 of the occupied males, or 82·1 per cent. of the total thereof occupied. The balance of them—viz., 250,626 men, or 17·9 per cent.—is made up by the remaining three groups comprising 12 "orders."

Of the occupied females, 586,841, or 81·8 per cent., of them were employed in domestic offices and services, in dress, in professional occupations, and in providing food, tobacco, drink, and lodging. The balance of them—viz., 132,490 females, or 18·2 per cent.—is made up by the remaining four groups comprising 16 "orders." In London in 1901 the greatest number of occupied men was employed in the conveyance of men, goods, and messages to the extent of 243,924, or 17·4 per cent., of the total occupied men, and the greatest number of occupied females was employed in domestic offices and services to the extent of 328,337, or 45·8 per cent., of the total occupied women. It is a case of transportation and domestication. The book then proceeds to deal by means of diagrams and tables with the proportion of the various orders of the occupied in the 29 metropolitan boroughs, of which Islington, Lambeth, Stepney, Camberwell, St. Pancras, and Wandsworth, in descending order of magnitude, include over one-third of the population of the county of London, and of which Wandsworth, Woolwich, Lewisham, Camberwell, Lambeth, Greenwich, and Hackney, include over half the acreage. The proportion of males to females varies greatly in the different boroughs. Thus in Kensington there are more than three women to every two men, but in Woolwich men outnumber women, which is doubtless due to the numbers at the Arsenal and in the army. The first general feature is the predominance in the boroughs of the same orders as in the county as a whole. As regards domestic service a table shows that in Hampstead there were 16,998 families or separate occupiers and 13,843 domestic indoor servants, male and female, and in Kensington 38,349 families and 30,670 servants—that is, 80 per cent. of the families had servants, whereas in Shoreditch only 5·7 per cent. of the families had servants. In the general or local government of the country there were engaged eight males to one female. Men engaged in the defence of the country were distributed mainly at Woolwich, Westminster, Greenwich, Kensington, and St. Pancras.

Those males occupied in "professional occupations and their subordinate services" are distributed chiefly among the following boroughs in order of their importance: Lambeth, Islington, Kensington, Wandsworth, St. Pancras, Westminster, Camberwell, and St. Marylebone; while the females thus occupied are chiefly resident in Lambeth, Islington, Wandsworth, Hackney, Kensington, and Camberwell. We are told that "the medical profession is one of the few occupations in which women outnumber men, this being accounted for by the large number (nearly 16,000) of women engaged in nursing." We presume that the term "medical profession" as here used is meant to include ancillary or "subordinate services." We are told also that "there are 92 women doctors and surgeons in London, as against 4709 men. The expression "doctors and surgeons" is quaint. It is stated that there are no women veterinary surgeons, engineers, or surveyors in London. The boroughs which have the largest proportion of male and female clerks are Islington, Camberwell, Lambeth, Hackney, and Wandsworth. The women have been gaining on the men at a rate probably too high to last and already form nearly 20 per cent. of the total. More than one-third of the men and more than one-fourth of the women engaged in tailoring in London are to be found in Stepney. Of men under "sanitary service" nearly half are found in Islington, Lambeth, Stepney, Paddington, and St. Marylebone. Speaking roughly, in the whole of London about one-third of the total unmarried women over 15 years of age are engaged in domestic services.

These are only a few of the interesting points. The book contains numerous diagrams and we agree with Mr. Loch that "to read it well the text and pictures have to be studied together and then recast in the mind so as to form living 'pictures' of the industrial life of the country, or of the metropolis, or of the metropolitan boroughs."

LIBRARY TABLE.

On the Evolution of Wound Treatment during the Last Forty Years. By Sir HECTOR CLARE CAMERON, M.D. Glasg. Glasgow: The University Press. Pp. 98.—Under this title are published the two James Watson lectures delivered in 1906 which were then briefly reported by our Glasgow correspondent; their issue in book form is opportune, for in a year that has heard much said in Lord Lister's honour no better tribute to his epoch-marking work has been paid than is afforded by this book. Its distinguished author had the privilege of assisting Lord Lister in his pioneer work at Glasgow, and these lectures have passed under the eye of the master himself, so that the record which they give of the evolution of modern surgical methods is doubly trustworthy. Sir Hector Cameron is very naturally a firm adherent of the true Listerian methods and deprecates the differentiation of a so-called "aseptic" school of teaching; he urges that the reaction that caused it was entirely due to a misconception of Lister's methods which were successfully practised by their author until he retired from practice 11 years ago, and gives his own experience to show that simple "antiseptic" methods are as safe and trustworthy as, and far less cumbersome than, those which have called into existence the elaborate machinery of the modern operating theatre. He points out that the criticism so often passed on Lister's earlier methods of carbolised "putty" and shellac dressings, that these were devised to seal up wounds, arises from a complete misconception of their application and gives their inventor the credit of introducing the now universally employed open-meshed gauze for surgical dressings. A very interesting note by Lord Lister is appended on the preparation of the perfected "double cyanide" gauze, in which he gives good reason why this dressing should be moistened in carbolic and not perchloride lotion. The story of Lister's final abandonment of the carbolic spray, when he at length became convinced that it was not necessary, eloquently testifies to the splendid absence of prejudice that he has shown throughout his life work. This little book is a fascinating addition to recent surgical history and may be very profitably read. We are surprised at the author's statement on p. 30 that cat-gut is now almost universally employed in tying arteries; this is certainly not the case in London.

Glimpses of American Surgery in 1906. By C. HAMILTON WHITEFORD, L.R.C.P. Lond., M.R.C.S. Eng. London: Harrison and Sons. Pp. 63. Price 2*s.* net.—The author of this little book has jotted down the impressions of the practice of surgery in America that he gathered during a adherents of the old empirical methods of Italy. The writings of Pliny and Celsus in the days of the empire are valuable storehouses of information as to the history of medicine and show the advances made by the practical Roman mind when stimulated by Greek theory, and still later the names of Aretæus, Rufus, and Soranus form landmarks on the road of progress. Finally, by the genius of Galen the scattered facts and theories observed and elaborated by many predecessors were united into a complete methodical system and his works remained until comparatively recent times the recognised authority in all medical matters.

Professor Neuburger has written an interesting, indeed a fascinating, book, and we shall await with impatience the appearance of the second volume which will presumably deal with mediæval medicine and bring us through the dark ages into the dawning light of the Renaissance, and finally to the wonderful illumination of all the sciences which was the glory of the past century. We can only hope that the second volume will equal the first in merit and that the whole book will find a translator into our own language capable of doing justice to the excellence of the original.

Hypnotism or Suggestion and Psychotherapy. By Dr. AUGUST FOREL. Translated from the fifth German edition by H. W. ARMIT, M.R.C.S. Eng., L.R.C.P. Lond. London: Rebman, Limited. 1906. Pp. 370. Price 7*s.* 6*d.* net.

THIS book is the first English edition of Dr. Forel's work on Hypnotism and is a translation of the fifth edition of this writer's well-known work. The opening chapter is, as the author states, of a theoretical nature and much psychological deliberation is required in order to grasp it. After briefly referring to "The Theory of Mneme" of Richard Semon, he rapidly reviews certain data which go to prove that we have no right to presume that consciousness itself has no part in the activity of the brain, nor is it correct merely to study the phenomena of superconsciousness for "the contents of our superconsciousness is always influenced and caused by hypo-conceived activities of the brain." He devotes several pages to the study of Dualism and Monism. He speaks of "monistic identity" rather than psychophysical parallelism and brushes aside as scientifically untenable the dualistic hypothesis. He makes a distinction between "pure scientific monism" (the hypothesis of identity) and "metaphysical monism." The latter teaches that there is nothing "psychical" without being at the same time "physical"; further, there is no "matter" without "energy" and no "energy" without "matter," consequently there can be nothing "soulless" (Unbeseeltes) in the world. The "hypothesis of identity," according to Dr. Forel, is not so wide, for "it is content to accept the identity of being of every psychical phenomenon, which is available for direct psychological observation, with its so-called brain-physiological correlative, and leaves the hypothesis of the 'soul' to metaphysical speculation." The second chapter deals with the conditions of consciousness, and reference is made to some personal researches of the author.

Under General Remarks on Hypnotism Dr. Forel briefly reviews the theories held by the various schools on this subject. He casts aside "Mesmer" and the "materialisation of spirits," and equally objects to the somatic theories; and finally concludes his remarks on this subject by saying, "there is therefore only one theory which stands in accord with the scientifically assured facts of hypnotism, and which explains the same satisfactorily, and this is the 'suggestion' theory of the Nancy school. All the others are built on misconceptions." When discussing sleep Dr. Forel states that "the relationship of hypnosis to normal sleep is unmistakeable." Although agreeing that in many ways sleep-consciousness appears to resemble hypnosis, viewed from the evolutionary standpoint the association between the two is difficult to connect. Is it due to auto-suggestion that the infant sleeps? It certainly cannot be the result of habit when it occurs in the opening hours of a child's existence, however much of a habit it may ultimately become. The author deals with many interesting subjects in the chapter on Suggestion; especially instructive are the sections on resistance of the hypnotised person, amnesia, suggestion as to time, "hallucination rétroactive," or suggested falsification of memory and its relation to those false accusations so commonly made by insane persons. In a subsequent chapter, when discussing suggestion and disorders of the mind, the author writes: "I cannot emphasise sufficiently that suggestibility is an absolute normal characteristic of the normal human brain," and he strongly controverts the Charcot school who define hypnosis as a form of hysteria.

Dr. Forel differs from an authority such as Wetterstrand in his belief in the efficacy of hypnosis in cases of epilepsy, for he considers that only a limited number of these cases are curable by suggestion. The author makes a strong reply to Dubois's book entitled "Les Psychonévroses et leur Traitement Moral" and severely criticises many of this writer's opinions. In the chapter on Hypnotism and Psychotherapy Dr. Forel records many interesting cases which he claims to have cured by hypnotic suggestion and these cases consist of persons suffering from disorders of the menstrual function, constipation, insomnia, and so on. The author makes a direct attack on medicinal therapy and directs against it a scathing criticism. A certain amount of what Dr. Forel states may be true but he is too carried away in the belief in his own subject to be free from bias. On p. 188 we read that "of all people the insane are the least suggestible, and those whose mental disturbances are severe are usually absolutely unsuggestible." Therefore even from Dr. Forel's standpoint they are fair persons on whom to watch the effects of drugs, for here we can largely eliminate the power of suggestion, and yet unfortunately for his argument drugs act with equal potency on the insane as on the sane. The author is too reckless in his statements, for in his annoyance at the many unwarrantable charges that have been from time to time hurled at the school of "suggestion" he makes equally extravagant statements which would be difficult to substantiate. Referring to the subject of crime in its relationship to hypnosis the author states that he is convinced "that every conceivable crime may be committed on a hypnotised person, provided that a higher degree of hypnosis is attained." Nevertheless, he believes this danger can be over-rated as it is possible by suggestion to protect the hypnotised from the influence of unscrupulous persons. We cordially agree with Dr. Forel when he states "that public exhibitions of hypnotised somnambulists ought to be rigidly prohibited on the ground that they represent a gross nuisance which is detrimental to public morals and public health."

Except for the chapter on therapeutics we have no hesitation in recommending this work as a useful text-book on hypnotism, as it contains much valuable information, and Mr. Armit can be congratulated on his careful translation.

Employment Pictures from the Census. By M. G. SPENCER and H. J. FALK, M.A. With a Preface by C. S. LOCH, D.C.L., LL.D. London: P. S. King and Son. 1906. Pp. 101. Price 2*s.* 6*d.* net.

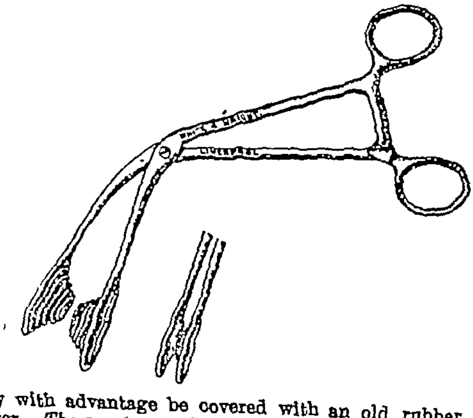
THIS book must be read with imagination as, in the words of the writer of the preface, "the figures are people—men and women—they are a vivid interpretation of life." We cull from it the following particulars. The total population of the County of London on March 31st, 1901, was 4,536,541 persons, comprising 3,598,253 persons older than ten years of age and 938,288 children under that age. The numbers of each sex were, of the older persons, 1,924,368 females and 1,673,885 males; of the children, 470,088 girls and 468,200 boys. As regards occupation, of the females 1,205,037 are classed as "unoccupied" (we do not know what the ladies themselves would say to this) and 719,331 examination and give directions for the collection of specimens of blood, sputum, diphtheritic swabs, and the like. The Post-Office regulations for the transmission of such substances by post are also given in full.

The Gentleman's Magazine.—The number for the current month has some very interesting articles. Mr. Lewis Melville recalls the career of that Frederick Prince of Wales of whom his father said, "My dear first-born is the greatest ass, the greatest liar, the greatest canaille, and the greatest beast in the whole world, and I heartily wish he was out of it." This is a hard verdict but it must be said that "Fred, who is dead," was not an estimable character. Mr. Carl Bock's article upon Chinese Beggars will be quite news to many. They have an official chief who has an income of about $15,000 per annum. Again, there are Imperial Beggars who are descendants of the ancient Ming dynasty. They "obtain a livelihood by swearing false oaths in court." Mr. C. W. Brodribb gives us a little dialogue between an Incunabulum (which, we may remind our readers, is the title given by German bibliophiles to an early printed book) and its owner, the book in question being a Tacitus, and Mr. C. H. Dant describes the ceremonies of that curious survival of ancient folk-rites, the Helston Flora Day.

New Inventions.

"FINGER-GRIP" FORCEPS.

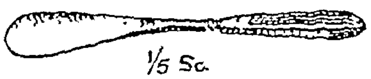
THESE forceps are intended to take the place of the finger and thumb in grasping any organ, such as the uterus, without damaging it. The blades terminate in oval rings into which are fixed cone-shaped springs. The apposition of these resembles the action of the "pads" of the finger and thumb in grasping and holding a soft organ. The blades may with advantage be covered with an old rubber glove finger. The great superiority they possess over the ordinary finger-grip of an assistant is security of grasp and the small amount of space occupied—that is to say, the hand of the assistant is not in the way. They have been made for me by Messrs. White and Wright, 93, Renshaw-street, Liverpool, and may be obtained in two sizes.



W. BLAIR BELL,
Assistant Gynæcological Surgeon, Royal Infirmary, Liverpool.

A PERINEAL "HORN."

Messrs. Fannin and Co. of Dublin have made to my design a simple instrument which may be called a perineal horn. It is practically the principle of the shoe-horn reversed. I have put it to many tests and am convinced that by its use rupture of the perineum will become a complication of much less frequency. In every case in which it has been used the perineum has never caused the slightest anxiety and needles and sutures are now omitted from my midwifery bag. The action of the perineal horn is that of a protector to the maternal tissues and a distributor of the pressure over the internal surface, preventing that initial rupture of the wall of the vagina of which the perineal tear is only the outward and visible sign. It will be observed that the rent takes place generally after the birth of the forehead and occurs simultaneously with the elastic rebound of the perineum. The perineal horn inserted between the child's face and the posterior vaginal wall takes all undue strain off the tissues, internal and external, equalises the pressure, and affords a smooth surface along which the child's face glides. By manipulation the pressure on the thinned-out margin of the perineum can be transmitted posteriorly.



JOHN F. ELLIOTT, L.R.C.P. & S.Irel.
Verulam, Natal, S.A.

ASYLUM REPORTS.

Kingseat Asylum, Aberdeenshire (Annual Report for the Year ending May, 1907).—The second annual report on Kingseat Asylum has just been issued by Dr. H. de M. Alexander, the medical superintendent. The total cost of the asylum at May 15th, 1905, amounted to £125,335. During the year ending May 15th last there was added to the providing account the sum of £5515 for the improvement of grounds, &c., making a total cost of £130,851 at that date. For the year ending May 15th last the total cost of maintenance amounted to £9471 and the average number of patients for the year being 375, the cost of maintenance per patient was £25 6*s.* 5½*d.* The reports on the asylum by the Commissioners in Lunacy continue to be satisfactory. On Dec. 31st, 1906, there were on the register 412 patients, of whom 216 were men and 196 were women. The most prevalent forms of mental disease among admissions were acute melancholia, acute mania, and delusional insanity due to alcohol. Six patients, all men, were admitted suffering from general paralysis of the insane. Among the assigned causes of insanity 29 patients were hereditarily predisposed and eight had suffered from one or more previous attacks. Among the physical exciting causes alcohol accounted for 18 cases, pregnancy and lactation for seven, general paralysis for six, acquired epilepsy for three, influenza for three, acute rheumatism for one, and injury to the head for one. Neurotic inheritance was probably present in all cases where the exciting cause of the mental attack was attributed to alcohol, as in those cases where inquiry into the family history proved futile the presence of neurotic stigmata in the individual told its tale. In connexion with moral causes five were assigned to emotional stress. The discharges during the year numbered 71. 29 men and 26 women were discharged recovered. The percentage of recoveries on the admissions was 41·6. Of those discharged unrecovered five men and three women were transferred to other asylums, three men and four women were "boarded out," and one man was discharged by escape—this man broke his parole and not being taken back within the statutory period of 28 days he was discharged. The deaths numbered 34—18 men and 16 women. The chief causes were pulmonary tuberculosis, senile asthenia, and valvular disease of the heart. Tuberculous disease of the lungs was definitely ascertained on admission in only one of the seven patients who eventually died from that disease. It must be remarked, however, that in the insane it is almost impossible to diagnose the incipient stage of tuberculous disease of the lungs. All these patients suffered from incurable mental disease and from those particular varieties of chronic insanity with which tuberculosis is unfortunately so often associated. Three accidents occurred to patients during the year. One was a case of fracture of the humerus, another a slight accident in the laundry, while the third was a case of ruptured intestine caused during a struggle between a warder and a refractory patient. Into this last case the usual inquiry was held and no blame was attached to the attendant. On Dec. 31st, 1906, there were 86 vacant beds, 33 male and 53 female, and although the decrease in the admission-rate for the year must be regarded as exceptional, nevertheless the accommodation at Kingseat Asylum is ample to meet the requirements of the district for some time to come.

visit to that country last year. Many years ago, when the late Frank Buckland's "Curiosities of Natural History" was issued, one reviewer remarked, "It reads like the contents of a note-book thrown out pell-mell," and we feel inclined to repeat that saying of the present small work, with the proviso, however, that this was probably just what its author intended. Most of the observations refer to differences of detail between English and American methods and they include some interesting information, especially that about the "Mayo clinic." The author's conclusion is that "American surgery is, with one notable exception—that of the treatment of the vermiform appendix—of the highest class, being based on logical reasoning and common sense." We acquiesce in his exception, at least as far as that hospital is concerned of which Mr. Whiteford remarks: "A grand total of 1031 appendices removed from 2727 patients."

The Poetical Works of John Keats. Edited by H. BUXTON FORMAN. The Oxford edition. London: Henry Frowde. 1907. Pp. 486 and index. Price 3*s.* 6*d.*—Medical men have not infrequently written verses and some have written poetry and there is at least one medical real poet at the present day. But of all medical poets Keats stands on Parnassus' top and we are most grateful to both Mr. Forman and Mr. Frowde for this admirable edition. It consists of the whole of Keats's known works in verse, with footnotes giving variorum readings, a most interesting introduction, two portraits, and facsimile titles, so far as the type goes, of Keats's three books. We hope that "The Oxford" Poets will eventually include an edition of Cowley, who was both a poet and a D.M. of the University of Oxford, though as he obtained the degree "by order of the Government," it is possible that his medical knowledge was not profound.

Notes on Hastings and St. Leonards. By A. SCARLYN WILSON, M.B., D.P.H. Cantab., Medical Officer of Health of the Borough.—This little brochure sent to us by the mayor of Hastings gives good reason for the claim of that old town to be considered a fine health resort; indeed, such a reminder can hardly be necessary to anybody who has spent a winter in St. Leonards and basked in December or February sunshine on the "White Rock" parade, but to others it gives the information that the Campbell Stokes' recorders show a sunshine record during the last five years which alone serves to recommend it to invalids. The meteorological data supplied by Mr. H. Colborne, M.R.C.S. Eng., the borough meteorologist, are very full. An attraction that Hastings can also claim for those not confined to the town by ill health is the beautiful and interesting nature of the country that constitutes its "*hinterland.*" We congratulate Dr. Wilson on the attractive arrangement of his brochure.

London Botanic Gardens. By PIERRE E. F. PERRÉDÈS, B.Sc. Paper No. 62. London: The Wellcome Chemical Research Laboratories.—This paper gives a most interesting account of the development and present conditions of the various London Botanic Gardens—i.e., the Royal Horticultural and Botanic Societies' Gardens, the Kew Gardens, and the delightfully named Chelsea Physic Garden. It is to the last and oldest that half of the book is devoted and we are told in the introduction that this and all the other public botanic gardens owed their inception to the collections of private herbalists in the seventeenth century. The Chelsea Garden was founded by the Society of Apothecaries of London in 1673 and in 1722 Sir Hans Sloane, the illustrious President of the Royal College of Physicians of that date, who was the lord of Chelsea Manor, presented it, under certain light conditions, to the Society, "to the end," as the deed of conveyance has it, "that the said garden might at all times thereafter be continued as a physick garden, and for the better encouraging and enabling the said Society to support the charge thereof, for the manifestation of the power wisdom and glory of God in the works of the creation, and that their Apprentices and others might better distinguish good and useful plants from those that bore resemblance to them and yet were hurtful, and other the like purpose." The troublesome task of distinguishing between official specimens may well have been less irksome in that old-world garden than amongst the dried-up preparations that confront the student in the modern materia medica museum. It is pleasing to note that one of the duties laid down for the curator or praefectus horti was to accompany students in summer "herborisings" or botanical field days when he was "desired to use his best endeavours to preserve strict decorum among his pupils, and for directing and confining their attention solely to the intended business of the day"—a very necessary injunction, we have no doubt. The history of the gardens up to the present day including their re-establishment as an adjunct to the botanical schools of London under a committee is fully given; it is interesting to note that the latter includes *ex-officio* the Earl of Cadogan as the lineal descendant of Sir Hans Sloane whose statue in the gardens still testifies to his ancient generosity. The other botanical gardens of London are well described and lists are given of the medicinal plants occurring in all of them. The paper is well illustrated with reproductions of photographs and plans which include an elaborate eighteenth century "survey" of the Chelsea Garden. The author and the publishers are to be congratulated on having issued such an acceptable paper.

JOURNALS AND MAGAZINES.

The Journal of Mental Science.—The number for April contains the Morison lectures, by Dr. A. R. Urquhart of Perth. The subject of these lectures this year was Insanity, with Special Reference to Heredity and Prognosis. The first lecture is entitled "Prolegomena," the second "Statistics," and the third "Somatic Correlations and Résumé." The next original article is by Dr. W. W. Ireland on the Psychology of the Crusades. In this paper he gives examples of the great credulity of the people in the Dark Ages. This article is followed by an interesting and instructive paper by Dr. J. F. Sutherland, Deputy Commissioner in Lunacy for Scotland. The subject is Recidivism Regarded from Environmental and Psycho-pathological Standpoints. He introduces his subject by saying that "Recidivism is the French-coined term most appropriate to express the persistent, reiterated lapses of the same individual in that small section of habituals found in every country, both among criminals engaged in serious crimes against person and property and among petty offenders, whose delinquencies or misdemeanours are drunkenness, public disorder, prostitution, and vagrancy." Dr. G. F. Barham of Claybury Asylum writes a short paper on Notes on the Management and Treatment of the Epileptic Insane, with a Special Reference to the NaCl-free (or "Hypo-chlorisation") Diet. He refers to the difficulty of carrying out this treatment in a large asylum; on the other hand, he points out that something can be done in a modified form. For instance, he found that by the simple substitution of sodium bromide for table salt the results were distinctly encouraging both in diminishing the number and the severity of the seizures and in improving the general behaviour of the patients so treated.

The Journal of Clinical Research. No. 1, Vol. I.—We have received the first number of this journal which is the official organ of the Clinical Research Association, Limited. It is intended to issue the journal periodically at intervals of about three months. Among the contents of this number is an article by Dr. Nathan Raw upon Human and Bovine Tuberculosis, with Reference to Treatment by Special Kinds of Tuberculin. Other articles deal with the methods of collection and preservation of morbid growths and tissues for season is at its height and within a small portion of the vast area of London are gathered men and women from every quarter, not of England alone but of the world, bent upon the enjoyment of the luxuries and the amusements that a great and wealthy city can supply. We doubt if the bad times to which we have referred with regret have greatly diminished the gaieties of the London season, and we would urge upon those who are filling with pleasant occupations every hour that they can spare from necessary rest not to forget their poorer brethren to whom no season brings recreation or leisure, and who, when they are overcome by accident or disease, must turn to the hospital as to the only friend who can save them from suffering and from death. We would press our appeal upon those who in the pursuit of pleasure visit our metropolis from foreign countries, asking them to remember how many of their humbler countrymen have made of London their temporary home in order to seek a livelihood in our teeming metropolis. Our hospitals close their doors to none on account of race or of religion; they seek no aid from the State or from the municipality, but from the charity of private individuals only; and we now ask those to whom such a system is new to consider what is meant by charitable institutions supported by the voluntary contributions of the benevolent, and to aid in a good work which cannot fail to win their admiration.

We are compelled to express the hope that those connected with London's commercial enterprises will make a special effort lest their annual contribution to the Metropolitan Hospital Sunday Fund falls below its usual level on account of circumstances to which we cannot shut our eyes—the fall in securities, and general feeling of unrest in the world of labour. We must also dwell briefly upon the loss which death has inflicted upon the hospitals and upon the Fund in the removal of their staunch and generous friend, Mr. GEORGE HERRING. No one has stepped forward to repeat his challenge of past years, under the terms of which he paid to the Fund a sum equal to one-fourth of that collected in the places of worship of the metropolis. Perhaps emulation of his princely generosity was not to be anticipated, but we must point out how much the hospitals will suffer by his death, in spite of the generous provisions of his will, unless an effort be made by those who survive him to increase their gifts. With many this should not be difficult, and there must be thousands of others having the means to give who in past years have afforded no support at all to the Fund, but who if urged by those having influence with them would, perhaps, give generously. We ask those who do not forget their own offering to use their influence to increase the gifts of others and to insure that they shall not remain ignorant of what "Hospital Sunday" implies. And with the suggestion that all should induce others to give in addition to contributing themselves we cannot but associate the name of one dear to ourselves. In the late Mr. WAKLEY, Senior Editor of this journal, as in Mr. HERRING, the Metropolitan Hospital Sunday Fund in the past 12 months has lost a true friend, and we point to the issue of our annual supplement year after year by him and under his supervision to show how fully he believed in the efficacy of persuasion exercised on behalf of charity and how practically he brought persuasion to bear where it might take effect.

Garden Suburbs and Garden Cities.

THE word "suburb," and still more the adjective "suburban," call up to the mind a picture of much that is commonplace, philistine, and even positively unlovely. Now suburbs, especially those of our provincial capitals, are often picturesque, and their inhabitants are in bulk as intellectual and as progressive as their fellows dwelling actually in the cities. But these facts are obscured by our recollections of the outskirts of many large towns with their long straggling lines of monotonous small houses, without form and without organic unity. We have often pointed out in THE LANCET that this mean and depressing environment is not essential to our town development, and have described with some detail the attempts now being made to show how the evils, practical as well as æsthetic, which characterise our suburbs no less than our large towns are due to the utter want of thought and system with which we allow our residential centres to develop. Given the opportunity of laying out some portion of the outskirts of a town upon a rationally conceived plan, many of the evils connected with housing would disappear of themselves. That there is no intrinsic difficulty in carrying this out is shown by the fact that this principle is already being acted upon at Hampstead where a few weeks ago "The Hampstead Garden Suburb" made its departure in town development, and where this week the foundation-stones of the first buildings were laid, as we report elsewhere. "The Hampstead Garden Suburb" is an estate of some 300 acres which has been bought by a company, the Hampstead Tenants' Society, and which is being held in trust for the community. Instead of allowing the speculative builder to erect upon the land as many small houses as municipal regulations will permit, employing an architectural style and a building standard that will allow of the maximum profit to the vendor of the houses, certain parts of the estate are ear-marked *ab initio* for gardens and open spaces, and these can never be built upon. In addition suitable sites for the schools, the bakery, washhouses, and shops have been decided upon before any building is begun. In this way symmetry can be secured as well as the requirements of hygiene. There will not be more than eight houses on the average to the acre of land held by the Hampstead Tenants' Society, so that the occupants will have adequate breathing space. By such systematic planning it is easy to preserve the natural features of special beauty of any building site, and treated in this way the environs of a large town may become not only health-giving but attractive to the eye and a source of pleasure and pride to the inhabitants who though not all of the same social class will be drawn together by a common and pleasant desire to live in a beautiful environment. For the aim of the garden suburb is to provide not for one class only but for many, so that while a large area may be devoted to workmen's cottages, other sites would commend themselves for the erection of larger houses. Most suburbs by providing for one class only add to the architectural uniformity a moral and intellectual monotony, and thus the segregation of classes which is so serious an evil of modern city life becomes still further accentuated.

On similar principles the Garden City at Letchworth is being developed and we make no excuse for returning to

THE LANCET.

LONDON: SATURDAY, JUNE 8, 1907.

The Metropolitan Hospital Sunday Fund.

TWELVE months have gone by since last we pressed the claims of the Metropolitan Hospital Sunday Fund upon the public to whom we address ourselves upon this annual occasion rather than to the narrower circle of our professional readers. Our supplement, published in last week's number of THE LANCET, has been issued and is doing its share, we venture to hope, in stimulating the generosity of subscribers and in producing a result worthy of the great cause for which we plead. To-day we can scarcely do more than reiterate with renewed earnestness that which we have said on other occasions, for it is not easy to find a fresh argument or a fresh ground of appeal where the features of the case presented by the advocate vary so little from those which have been dwelt upon already. Even the year that has passed since the Metropolitan Hospital Sunday Fund last held its collection, filled as it has been with events of political interest for the nation, and with incidents which may long be memorable to individuals as affecting their personal lives and fortunes, contains little to which we can refer in emphasising the need of the hospitals of London for loyal and ungrudging support. Their year's chronicle contains no events of sensational nterest to arrest the glance of the passer-by; they have no story of startling achievement or of unusual success to which they can appeal, in order to unloose the purse-strings. For them the past twelve months have brought, as ever, merely 52 weeks of earnest, anxious, useful work in the cause of charity; weeks in which health has been restored to the suffering poor, in which pain has been relieved, and in which death has been averted; but although the aid which medicine and surgery bring through the medium of the hospitals into the homes of the helpless may mean renewal of life to its actual recipients, the world at large has little opportunity of estimating that which has been achieved. It has also no means of judging what restored health may mean when it is that of the wage-earner, toiling to support a family, or of the mother tending that family. Any alleged shortcoming on the part of a hospital can readily be noted and extensively advertised. When it is publicly stated that a patient has not been able to obtain admission to an institution already filled to overflowing and unable through lack of money to increase its accommodation, then, indeed, we see and hear plenty of unfavourable comment, but the comment is usually based upon a wholly false impression of the facts and takes no account of the lack of funds or of other causes arising out of poverty that impose limits upon the beneficence of all charitable institutions. Censure is more readily listened to than praise, and it is far easier to make known the possibly causeless complaint of an individual than to blazon abroad the everyday tale of duty performed with monotonous efficiency If there be failures on the part of the hospitals of London to achieve perfection, such as there must be where human agencies are concerned, the promotion of sound organisation and economy is ever the care of the Metropolitan Hospital Sunday Fund, and the causes of failure could be for the most part removed by unloosing the public purse-strings.

If we are unable, however, to point to anything but a year of ordinary work on the part of the hospitals we do not for a moment suggest that the year has not been a period of progress on their part, and we feel that the sympathy of all should be with those who energetically do their daily duty of charity without vaunting their performances and with those who aid the gradual but sure advance of medical science without lending themselves to anything in the nature of dramatic display or of sensational advertisement. The greater number of those who live throughout the year in London and in the districts surrounding it, whether they be rich or poor, do so in order to earn their living, or to add to wealth already accumulated in London's countless trades and vast industries. It is with the captains of industry, mainly, that the power lies to maintain the income of the Metropolitan Hospital Sunday Fund at the high level which it has reached during past years, because into their hands flow during the year the proceeds of the mighty commerce of the greatest city of the world. At the same time we cannot ignore the fact that during the past 12 months a certain depression has been apparent, and that with many of those to whom we refer "times are bad," to use a popular phrase. With their anxieties we sympathise, but we would urge upon all, even though their financial circumstances may not be what they would wish them to be, and although the supply upon which they usually draw for the purposes of charity may be diminished, not to allow the hospitals to suffer thereby if any effort of self-denial can enable them to maintain their gifts to the Fund at their usual level. It is possible that some portion of their income may be usually divided between charity and pleasure. We would urge them in such a case to sacrifice their pleasures to some extent, rather than that charity should suffer loss; and in this we address ourselves not to those only whose revenues are large but to those whose yearly profits in their own estimations, or seen in the light of their ambitions, are but small. Let them think of those for whose sakes they are asked to give and remember that for them there can be no question of surplus when the week's wage is reckoned. Let them not forget those who in time of illness or injury would be helpless but for the aid given by the hospitals, those upon whose earnings from day to day their families depend for the supply of their daily needs. But although we may address ourselves first to that section of London's millions to whom London and London's suburbs represent home with all its associations or business with all its claims and emoluments, to the Londoners who should give for the benefit of their humbler fellow citizens, we do not forget the vast and wealthy crowd of those who flock to the metropolis in June in pursuit of pleasure before all other objects. The rose to about 70° in the south-east as well as in some districts in the north and north-west of England. The wind as it blew over the metropolitan area during this period was sometimes from the eastward, but in reality the air-current then prevailing came from a more southerly point of the compass and was only deflected into east as it arrived on this side of the Channel. These summer-like interludes were very enjoyable but they only served to render the subsequent relapse to abnormal cold the more disagreeable and the more perilous. The worst spell of cold occurred about Whitsuntide; during three days the thermometer in London and over the greater part of the country failed to rise above 51°, and on the fourth day only touched 52°. As the average temperature for the afternoon during that period of the month is about 62° it will be seen that the universal complaints against the weather at the holiday period were veritably justified. In Scotland and the north of England the weather was even more consistently cold, the occasional warmth in the south only reaching those districts in a modified degree or failing to affect them altogether. But certain parts of Scotland were capriciously hot; on the 26th, for instance, the shaded thermometer at Lairg in Sutherlandshire ascended to the high point of 79°. Owing to the few warm spells and to the absence of any abnormal frosts the mean temperature for the month was not as a rule much below the average, but the sunshine was almost everywhere gravely deficient, while the quantity of rainfall was generally in excess over some parts of the north and north-east of Great Britain, the aggregates being more than double the average amount.

The reason why we, as a nation, invariably introduce conversation with a stranger, and not infrequently with a friend, by remarks upon the weather is, of course, that in our so variable climate the weather is actually of prime importance to our lives. We have just had placed before us an interesting pamphlet[1] which may be regarded in a sense as a plea for more exact talking about the weather, and as such we bring it to the notice of our readers. About three years ago we gave some account of the scheme by which Mr. W. F. TYLER of Shanghai proposed to make exact comparisons of climates and this pamphlet further develops his scheme. He says that in a general sense the term climate indicates the idea of varying degrees of physical comfort or discomfort resulting from the local meteorological conditions. In mild climates, among which, despite our recent experiences, he includes the climate of the British Isles, the means of describing the combined effects of local conditions is generally limited to calling the climate either "bracing" or "relaxing," as the case may be. In tropical or semi-tropical climates, such as those encountered in China, a means of describing the varying degrees of discomfort is practically non-existent. The weather may be called "muggy," but the degree of mugginess can only be denoted by various inexplicit adverbial adjuncts. There are, however, very strong grounds for suspecting that temperature and humidity are the most important of the conditions that go to make up "mugginess." These can, of course be measured by ordinary physical methods with considerable precision, and Mr. TYLER has endeavoured to show how the varying bodily sensations associated with changes in the weather may be numerically expressed. For the purposes of this investigation it appeared necessary to invent a word indicating the sensation caused by a "muggy" climate and the term selected is "hyther" (a "portmanteau" word coined from hydrothermos). The "hyther" scale has for its limits the numbers 0 and 10. Limit 10 represents the very worst day an observer remembered to have experienced in China—hot, damp, and enervating; while limit 0 represents an ideal summer day—warm, of course, but bright and bracing, so that a person suitably clothed and not exerting himself unreasonably or unseasonably suffers no discomfort from the climatic conditions. On each day of the month of August, 1902, at Shanghai, 12 individuals at noon estimated the degree of "hyther." They were all persons of normal condition, regular habits, and equable temperament. Instrumented meteorological observations for the purpose of comparing with the estimated "hyther" were obtained from the neighbouring Zicawei observatory. When the estimated "hyther" numbers and also the readings of the wet-bulb thermometer were plotted on squared paper a remarkable correspondence between the respective graphic curves was apparent, and Mr. Tyler found that the relation between the "hyther" numbers (h) and the wet-bulb readings (w) was approximately represented by the equation—

$$h = \frac{w - 66}{3}.$$

Mr. TYLER reinforced his observations on the production of a sensation scale, founded on the estimations of the temperature of water by persons who dipped their hands successively into water at 43° F., at 120° F., and at the temperature to be estimated, but for his interesting observations in this direction we refer our readers to his record of his work. We have referred to it in connexion with a brief consideration of the disagreeable May which we have just experienced because it suggests to us that the scientific study of weather is not sufficiently pursued among us. We are most of us content in our frequent allusions to the subject to employ any inaccurate terms which come into our mouths, because meteorology is not really studied by a sufficiently large number of persons to make the carelessness of our phraseology noticeable.

Annotations.

"Ne quid nimis."

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

AT a meeting of medical men, biologists, and others interested in tropical diseases, which was held in London on May 10th, the Society of Tropical Medicine and Hygiene was duly constituted. Laws for the government and administration of the society were at the same time considered and passed and the first council was elected. The formation of a society to promote the study of the diseases of warm climates and to facilitate intercourse and discussion among discussion of the Letchworth experiment. It is one of great importance to the medical profession and its developments should be watched by our readers. The proceedings here are, of course, on a much larger scale than at Hampstead, for at Letchworth the estate purchased by the company was nearly 4000 acres and already in three years the population has increased from 300 to about 3000; there are some 400 houses upon the land and nine factories. At the outset about one-third of the whole area was set apart for building purposes, the remainder being designed to consist of gardens and open spaces within the city which will be surrounded by an agricultural belt like the rampart of a mediæval town. This agricultural belt will doubtless in the course of time be let for small holdings, the owners of which having thus a market at their very doors may be expected to find dairy farming a profitable undertaking. The essential point, however, is that the agricultural belt cannot be built upon, so that the ultimate size of the city is limited. That there is nothing chimerical in the idea is shown by the fact that this principle has been acted upon by such practical people as the Australians who have surrounded Adelaide with park lands in such a way that the town can only increase by making a sort of "knight's move" over these park lands. A similar method of treating the ring of land encircling a great city has been attempted in many American cities and in some instances the endeavour has met with great success. Both the Hampstead Tenants' Society and the managers of the Letchworth Garden City are paying special attention to the construction of workmen's dwellings, and it is hoped that the principle of a common kitchen and service for chambers may be introduced, if not actually among the cottages of workmen at least for that large class which can hardly afford to keep a servant and is yet incapable single-handed either of cooking satisfactorily or of providing for its household needs wisely. A plan with much to recommend it consists in building small houses round three sides of a quadrangle, the centre being occupied by a common kitchen and dining hall which might serve from 12 to 24 families. By paying a small sum towards the common kitchen a woman would not only be spared the trouble and worry of cooking the family dinner, but would be saved from the unnecessary expense which must always result where unskilled people engage in activities for which they are unfitted. We have recently called attention to the deplorable ignorance of the English women of the lower classes of the principles of domestic economy as applied to cooking, and division of labour is as applicable to domestic economy as to other things. The health of such colonies as those which we are considering must improve if one efficient cook is substituted for four bad ones.

[1] The Psycho-Physical Aspect of Climate with a Theory concerning Intensities of Sensation, by W. F. Tyler, F.R. Met. Soc., Assoc. Inst. C.E. Reprinted by permission from the Journal of Tropical Medicine and Hygiene, April 15th, 1907. London: John Bale, Sons, and Danielsson, Limited. Pp. 45 and four folding plates. Price 5s.

All the schemes for garden cities and garden suburbs should interest the medical profession, for who realises more clearly than the medical man, whatever may be his sphere of practice, how much disease, poor health, and ineffective life are due to the bad housing conditions which prevail in our large towns? No one can be more alive than the medical practitioner to the far-reaching opportunities which here present themselves for making a fresh start in our urban life and so removing the various conditions which foster the growth and hasten the development of disease. More air and sunshine, larger open spaces, fewer houses to the acre, and greater amenities of city life, must surely all make for an improved level of health. Consequently, it is to be hoped that wherever kindred movements are on foot medical men will give them their heartiest support. One immediate way of assisting this very practical method of reform would be to join the Garden City Association (Central Office, 601, High Holborn, London, W.C.) which has sister associations in France, Germany, Belgium, and America, and with its branches at Liverpool, Manchester, Newcastle, and Glasgow advocates these principles throughout the length and breadth of the land and aids effectively in their actual carrying out. From this parent association have issued the two practical undertakings already mentioned and there are others in prospect. The Garden City at Letchworth by starting *de novo* with a well-thought-out plan shows how a modern town, instead of meriting Ruskin's description of it as a "congeries of bad building and ill living," may be an organic *whole, neither defying* the laws of æsthetics nor sinning against the rules of hygiene. The Hampstead Garden Surburb should indicate the lines on which existing towns can extend and develop in a sane and rational manner for the benefit of all.

An Inclement May: the Psycho-physical Aspect of Climate.

It is a well-established fact, proved as well by common and shuddering observations as by the statistics of meteorologists, that these islands are more liable to suffer from east and north-east winds during the spring than at any other time of the year. May is more frequently the selected time than April, while in March, despite popular notions, the cold current is likely to be from the north or north-west rather than from the north-east and east. No one will deny that the May which has just finished its course was a disappointing as well as a very trying month, and an examination of the daily charts of weather published by the Meteorological Office makes it clear that the inclement condition was due to the wretched persistency with which the atmospheric pressure remained greatest over the Icelandic and Scandinavian region and lowest over the Spanish Peninsula, France, and Germany. This distribution of pressure is exactly the reverse to that obtaining over these parts of the earth's surface during the greater portion of the year and, of course, compels the air to flow from the Arctic north-east of Europe across the British Isles. There were certainly occasions during the month when a temporary displacement of the northern anticyclone and the near proximity of cyclonic systems to our west and south-west coasts brought about winds from milder quarters, enabling the thermometer to rise to the normal and for a brief period far above it, but these leniencies were few. At the commencement of the month the wind was westerly to south-westerly, and from the 7th to the 12th there was a southerly current that brought up very warm air from the Mediterranean region and raised the shade temperature to 79° F. in London and to 80°, even a little above it, in several parts of the home counties and in the north-east of England. There was also another short interval of warmth from the 23rd to the 25th, when the thermometer be torn to shreds and converted into flock by the machine appropriately known as "the devil." The resulting mass, of course, should be thoroughly washed and scoured but that process obviously makes it more costly and so sanitary procedure is ignored and all sorts of abominations are mercilessly stuffed into the mattress. By the courtesy of Messrs. Maple and Co. we had the opportunity of inspecting their bedding factories and of watching the processes or series of processes which bed-stuffing of varying qualities goes through before it is considered fit for the purpose of stuffing mattresses. The raw material comprises hair, feathers, torn up carpets, rags, and so forth, all of which are carefully submitted not only to a cleaning process but also to a dust-extracting process also. During the teasing out of this material the operation is conducted within the field of an exhaust fan or cyclone, so that all irritating and easily scattered dust is effectually removed. Is it unreasonable to demand that all raw material destined ultimately to be used for filling bedding should be treated on the scrupulous sanitary lines indicated? We not only think not but maintain that some form of Government machinery should enforce such treatment.

THE SULPHUR FIEND.

THE smoke nuisance is not only a menace to health but threatens also to destroy our buildings. Even if scientific skill and energy, bearing in mind also economic considerations, are able to suppress the visibility or opacity of smoke, a quality which shuts out health-giving light rays, it still remains to eliminate the products of combustion of the sulphur which is contained in more or less quantity in all ordinary coal. It is bad enough to have the daylight screened from us by a pall of dense smoke and vapour, but it is probably worse when that atmosphere is charged, as it invariably is, with sulphurous and sulphuric acids, both irritating to a degree and destructive to many of London's interesting buildings. We are inclined to the view that after all the sulphurous outpourings of London's chimneys are more responsible for the ill-effects of fog than is any other factor. It must be remembered that during a fog there is practically no movement of the air of that kind which is calculated to attenuate or to remove these outpourings, and it has been estimated that quite, if not more than, half a million tons of sulphuric acid are emitted annually in London from the coal burnt in our fireplaces. The air is thus regularly reinforced with a corrosive chemical ready to do mischief to our throats and lungs and alike to the structure of our buildings. Limestone is converted into gypsum or sulphate of lime, a substance which is more voluminous than the native material and which readily powders and detaches itself, playing havoc with delicate mouldings and tracery. St. Paul's Cathedral and the Houses of Parliament are victims of the sulphur fiend. The rain descends and by the time when it reaches the buildings it has become a weak but nevertheless destructive solution of sulphuric acid. The surfaces are thus exposed year in and year out to a more or less continuous stream of acid washings. This is no case for palliative measures or a remedy but one calling absolutely for prevention. It is, however, of interest to mention one idea in regard to a remedy which so far has met with most pleasing success when applied to surfaces which have already been attacked. A solution of baryta appears to have the property of re-cementing together the particles of the decayed stonework and it is assumed that it acts by forming with the gypsum insoluble sulphate of barium, at the same time liberating lime which sooner or later becomes converted into carbonate, the substance of the original limestone, by absorbing the carbonic acid gas of the air. Professor A. H. Church gives an example of the success of this treatment in the case of the Chapter House at Westminster. "Before treatment a touch of the finger sufficed to bring away the surface of the carving; afterwards the stone was as sound as that newly quarried and harder." This sounds satisfactory enough but obviously it would be still more satisfactory if the destructive agent was never allowed to exercise its corrosive property, or, in fact, to have any existence at all. There can be no objection to washing the surfaces of buildings with baryta water but that does not solve the question of the injurious action of sulphuric acid on the health of man and of plants. We may cover our buildings, as has been suggested, with a veneer of impermeable or protective wax and thus preserve them from the inroads of sulphuric acid in the air but we still leave our respiratory tract open to the irritating action of "the London particular." We cannot wax our throats, our eyes, or our noses.

THE ADMINISTRATION OF ETHER BY THE DROP METHOD.

IN the *Maryland Medical Journal* for May Dr. S. G. Davis strongly advocates the administration of ether by the drop method which is adopted in St. Mary's Hospital, Rochester, and in several other American hospitals. It certainly possesses the great merit of simplicity. Dr. Davis places a piece of rubber protective over the patient's eyes to shield them from the vapour of the ether. Since he began to do this he has not had a single case of conjunctivitis due to ether. The face is protected with a moist towel or gauze which extends over the rubber tissue and around the chin. The inhaler consists of a wire frame like that of Esmarch's chloroform inhaler but larger, in order to give more space for mixture of air and ether. The air space under the frame should contain about 25 cubic inches—i.e., be about thrice that of Esmarch's chloroform inhaler. The frame is curved so as to fit the face closely. It may be covered with one or two layers of stockinette or with several layers of gauze. The best covering is about six layers of ordinary gauze which can be quickly applied and thrown away when done with. The frame should be boiled after use. The inhaler is applied over the face and the ether is administered drop by drop, very slowly at first, then gradually more rapidly as the patient is able to take stronger vapour. Finally, at about the time when he will not respond to questions, a moist towel or some gauze is wrapped snugly round the mask, leaving a small area in the centre for the free passage of air through the gauze. Thus the air is prevented from passing under the edges of the inhaler and is made to pass through the ether-laden gauze. The ether should not be dropped on more quickly than the patient can comfortably breathe it. Dr. Davis lays great stress on slow administration and advises the anæsthetist never to be in a hurry to produce unconsciousness and not to let the operator hurry or worry him. The patient, it is stated, will become unconscious in two or three minutes and will be ready for operation in about ten minutes. After complete anæsthesia is induced very little ether, dropped slowly but continuously, will suffice to maintain the proper degree of narcosis. The further duties of the anæsthetist consist in watching the respiration, pulse, pupils, and general condition, and in not allowing respiratory paralysis to be induced. The respiration should be quiet, with perhaps a slight snore. Panting and rapid, irregular, or stertorous breathing indicate that the patient needs more air. The pulse should be regular, full, and bounding. The pupils should be of normal size and quickly respond to light. Since adopting this method Dr. Davis has abandoned the chloroform-ether sequence, as he found that it presented no advantage over the simple administration of ether. Another advantage of the drop method which is those who pay special attention to this branch of medicine has long been desirable, but its inception on a sufficiently broad basis has only recently been found to be practicable. That end has, however, now been attained, the success of the movement having in a great measure been due to the approval and coöperation which it has received from the Schools of Tropical Medicine in London and Liverpool, from the Universities and other teaching bodies, from the Naval and Military Medical Services, and from the large and rapidly increasing number of physicians who are engaged in mission work and in the practice of medicine and hygiene in tropical countries. An interesting and important feature in connexion with the society is the active support which has been accorded to it by many eminent biologists, the value of whose assistance in their own field of research—by no means the least important department of tropical medicine—will not readily be overestimated. The acceptance of seats on the first council, by representatives of these various services, institutions, and interests, furnishes an effective guarantee as to the extent of the sphere of activity and as to the energetic and capable administration of the society. All registered medical men and others who are interested in the sciences related to tropical medicine are eligible for election as Fellows; and the council is empowered, for a period of six months, to elect without ballot, on application being made and on its being satisfied as to the eligibility of the candidates, a limited number of original Fellows. The annual subscription is one guinea, there being at present no entrance fee. The headquarters of the society have been established at 20, Hanover-square, London, W., where ordinary meetings will be held at 8 30 P.M. on the second Wednesday of every month except August and September. The first meeting of the society is fixed to take place on Wednesday, June 26th, at 8.30 P.M., when it is expected that the President, Sir Patrick Manson, will deliver an inaugural address, and objects of interest in tropical medicine will be exhibited. The first council of the society is as follows:—President: Sir Patrick Manson. Vice-President: Professor Ronald Ross. Treasurer: Dr. W. Hartigan, 4, Bond-court, Walbrook, E C. Secretaries: Dr. F. M. Sandwith, 31, Cavendish-square, W., and Dr. W. Carnegie Brown, 32, Harley-street, W. Councillors: Mr. Ernest E. Austen, Fleet Surgeon P. W. Bassett-Smith, R.N., Mr. James Cantlie, Dr. C. W. Daniels, Lieutenant-Colonel G. M. J. Giles, I.M.S., Mr. W. M. Haffkine, Dr. C. F. Harford, Dr. T. S. Kerr, Dr. G C. Low, Professor E. A. Minchin, Lieutenant-Colonel C. H. Melville, R.A.M.C., Professor G. H. F. Nuttall, Dr. L. W. Sambon, Mr. Arthur E. Shipley, Dr. J. W. W. Stephens, and Mr. Fred. V. Theobald.

THE PUBLIC ATTITUDE TOWARDS CONSUMPTIVES.

UNDER the heading of "Panic and Prejudice" Mr. W. K. McClure, writing in the *Westminster Gazette* has drawn attention to the growing tendency among a considerable section of the public to treat the sufferer from pulmonary tuberculosis almost as an outcast, or, at any rate, as one to be shunned from fear of infection. He very cogently and rightly points out that a wider recognition of the simple fact that infection is chiefly conveyed by careless expectoration would "do far more to prevent the spread of consumption than the callous ignorance which brands all consumptives as outcasts." The knowledge of the communicability of consumption from person to person so long disputed, but now so universally recognised, has resulted in a widespread misconception as to the mode of infection, in virtue of which no little hardship is inflicted upon the unfortunate sufferers from that disease. An instance of this is brought forward by Mr. McClure. He points out that the fear of infection has so taken hold of many people's minds that the warm health resorts of Southern Europe and Northern Africa are practically barred to those suffering from pulmonary tuberculosis. Mentone led the way in excluding them; some years ago the proprietors of first-class hotels agreed among themselves to refuse to receive guests known to be suffering from consumption on the supposition that their presence hindered the development of Mentone as a pleasure resort. Since then a similar action has almost been forced upon the hotel proprietors in other parts of the Riviera, so that practically consumptives can only visit these places when they conceal the nature of their illness. Mr. McClure states that inquiries were made in the autumn of 1905 and again last autumn at the principal hotels at every resort from Hyères to Rapallo as to whether consumptives were received, the reply in almost every instance being an uncompromising negative. One of the answers was a striking testimony to the reason underlying these refusals, for the hotel proprietor replied that many of the visitors to his hotel made it a condition that no one suffering from disease of the lungs should be taken as a guest. As Mr. McClure points out, "the pleasure seekers have made up their minds that consumptives must either remain in sanatoria in their own country, or if they come abroad go straight to the Davos valley and stay there." This attitude towards the unfortunate sufferer which Mr. McClure so rightly and so strongly deprecates is one with which the medical practitioner is very familiar. He is frequently asked whether it is not dangerous to retain the services of a tuberculous person, or, if he be attached to a hospital, often hears that the consumptive has been discharged from his employment owing to the fear of infection. Instances could easily be multiplied showing the growing tendency to treat the consumptive like the leper or to regard him as a pariah to be avoided in every way possible. Mr. McClure's thoughtful article deserves to be read widely. It cannot be too generally known that practically the only means of conveying the infection from one person to another is from the drying of sputum and its dissemination as dust containing tubercle bacilli, if we except intimate personal contact, such as kissing or occupying the same bed. Further, that given the most simple precautions in regard to the disposal of his sputum by the consumptive, the danger of infection is almost non-existent. The public have obviously a right to expect that such precautions shall be rigidly carried out, and in return it is their duty to treat the sufferer with the consideration and the sympathy which he deserves and not to increase his sufferings further by branding him as dangerous and to be avoided.

"LOATHSOME BED STUFFING."

OUR attitude on the above subject, as explained in several articles in recent numbers of THE LANCET, continues to attract the attention of the trade and it is gratifying to us to find so many representatives of the bed-furnishing industry giving hearty support to our views. We have consistently urged that the evil can be suppressed by a simple system of inspection of the factories where bed stuffing is made and handled. We are convinced that no respectable firm would resent this plan should it become part of a Government scheme for preventing this scandal. On the contrary, the great furnishing houses, we feel sure, would welcome such an innovation and the plan of control could be conducted without needlessly submitting their business to inconvenience. This, at any rate, is the opinion of one great furnishing house—namely, Messrs. Maple and Co. We understand from the representations made to us by this firm that the root of the mischief is simply and solely the disgusting policy of raking up the cheapest possible raw material. Any offensive rags, left off clothes, and so on, can

Linnæus is of course best remembered as a botanist and zoologist, the originator of the nomenclature named after him, but he was also much more. In the first place, he was eminent as a biologist: "he found biology a chaos, he left it a cosmos." Then, too, he was a traveller interested in folk-lore, and wrote an admirable book about the Lapps, among whom he journeyed for thousands of miles. Nor did he cut a mean figure as a practising physician. Indeed, his earlier associations are chiefly medical, and Stobæus, an eminent physician, was one of his kindliest patrons. There is much in the early struggles of Linnæus, his vivid character, his brilliant powers of observation, his passionate pursuit of science, and his enormous originality that reminds us of John Hunter. Both men were destined to conventional pursuits and were threatened with apprenticeship to mechanics. Indeed, Hunter was for a time a cabinet-maker. Both men early escaped by sheer force of genius from the influence of their environment, achieved an infinity of original work, and at length became shining stars in the firmament of time.

MR. BALFOUR AND POST-GRADUATE STUDY.

THE meeting of the Federal Conference on Education, which was held on May 31st, was occupied with a discussion upon universities and was remarkable in many ways. The views which were expressed as to the real function of a university, of the importance of post-graduate study, and of the necessity for interchange and reciprocity among universities were not new, for in point of fact they were a recurrence to mediævalism. But they were revivals. Chief among the many excellent speeches was, perhaps, that delivered by Mr. Balfour, which dealt mainly with the importance of post-graduate study. After a protest against the tyranny of examinations, he continued :—

> "But, at all events, let us rejoice in common that there is one branch of university work, of growing interest and importance, daily receiving more recognition from all that is best in the intellectual life of the country—I mean the post-graduate course. There the slavery of examinations is a thing of the past, the intellectual servitude in which the pupil has hitherto been is a thing he may put on one side; and he is in the happy position of being able to interrogate nature and to study history with the view of carrying out his own line of investigation and research, instead of being in a perpetual subservience to the idea whether such and such a subject is worth getting up for examination purposes, whether he may not have omitted to read with sufficient attention something which to him is perfectly useless, perfectly barren, perfectly uninteresting, but on which some question may be asked by a too curious examiner."

And further, he added that it was in connexion with the post-graduate course that there could be a communication between ourselves at home and the more distant parts of the Empire. "If," he said,

> "we can so arrange the post-graduate course of our universities that it will be thought a normal and natural thing for any man who has the talent and the time to devote his life to investigation, first, to get his education at one of the universities of his own country, and then to go and conclude that education in a post-graduate course in one of our colonies, how great will be the advantage, not merely to the student, but to the communities which will be brought together by a tie which may unite us all in a common interest in these higher subjects."

This is a noble ideal—one, moreover, which there should be no great difficulty in making a reality. In the Middle Ages the universities of Europe were free to all duly authorised scholars, and in many instances the teachers of one university were free to teach in any other university. In those days the curse of Babel was removed by the universal knowledge of Latin as a language common to learning. If this is so no longer, there exists for British students a number of universities in far distant lands where their own tongue is spoken, and in addition to the countries under the British Empire there is that great country allied to ourselves—namely, the United States of America. From our own particular point of view how much benefit would arise to humanity in general from the labours of a band of earnest students who could study the diseases of tropical climates in the universities of those lands where such diseases are prevalent. Much has already been done in this matter, but much also remains to be done. It is of good omen that the conference unanimously carried the following motion :—

> That it is desirable that a committee representing universities should be formed which should investigate the question whether it is possible to facilitate the exchange of information as to their courses and standards between the universities of the empire, and to take action accordingly.

We hope that this is but a prelude to an interchange of students and teachers among the universities of the empire.

PEPTIC ULCER FOLLOWING GASTRO-ENTEROSTOMY.

IN the *Cleveland Medical Journal* for May Dr. C. A. Hamann has reported a case of peptic ulcer of the jejunum following gastro-enterostomy, a lesion which has only recently attracted attention. A man, aged 48 years, suffered for some time from symptoms of gastric ulcer—pain, tenderness, emaciation, hæmatemesis, and hyperchlorhydria. Anterior gastro-enterostomy and entero-enterostomy were performed. The Murphy button was used in both anastomoses. Recovery from the operation was uninterrupted and the smaller button was passed, but on the twenty-second day epigastric pain began. An indistinct tender mass was felt in the epigastric and left hypochondriac regions. The patient was allowed to go home as his condition was not regarded as serious. He died rather suddenly 26 days after operation. The necropsy showed on the anterior wall of the jejunum just beyond its junction with the stomach a perforated ulcer about an inch in diameter with a sharply marked border. The button was *in situ* but the perfect nature of the union and the position of the ulcer showed that the button could not have caused the ulcer by pressure. The ulcer was exactly in the position where the highly acid gastric juice would come into contact with the intestinal mucosa. The gastric mucosa showed erosions but no round ulcer. There was also general peritonitis. The operation of gastro-enterostomy was introduced in 1882 but not until 1899, 17 years later, was the first case of peptic ulcer following it reported by Braun. In an extensive review of the subject Gosset collected 31 cases, mostly German.[1] Of these 29 occurred in males—a preponderance in striking contrast to the greater frequency of gastric ulcer in females. The ulcer occurred most often after anterior gastro-enterostomy (15 cases out of 27). It occurred once after Roux's operation, four times after anterior gastro-enterostomy with entero-anastomosis, six times after posterior gastro-enterostomy, and once after this operation with entero-anastomosis. But it must be remembered that the anterior operation has been performed more often than the posterior, at any rate in Germany, where most of the cases have been recorded. Mr. A. W. Mayo Robson has pointed out that many cases must have been unrecognised because perforation did not occur and that in many others death must have resulted from abscess formation or in other ways, the adhesions and other complications obscuring the parts, so that at the necropsy the true nature of the affection was not ascertained. The time after operation at which symptoms of ulceration appeared varied from seven hours to ten years. Ten of the cases were fatal, 19 terminated in recovery, and in the remaining two the result is not stated. In all the operation was performed for benign disease. Of 14 cases in which the method of operation is stated suturing was performed in nine, the Murphy button was used in four, and a bone bobbin in one. In 17 out of 21 cases there was hyperchlorhydria. In consequence of the apparent relation between hyperchlorhydria and post-operative ulcer the administration of sodium bicarbonate after operation has been recommended. Most, if not all, the ulcers have occurred in the jejunum. The duodenum seems claimed is that vomiting is much diminished by its use. This method has been extensively employed in Europe but has few advocates in Great Britain. Dumont's ether mask is practically identical with that described by Dr. Davis and has been employed in Berne and elsewhere in Switzerland. The plan is wasteful both in the matter of time and material and does not appear to offer any advantages over the nitrous-oxide-ether method introduced by Clover. It is, perhaps, easier for the advice to be given that the anæsthetist should not allow himself to be "hurried" or "worried" by the operator than it is for it to be taken. In busy hospital practice the loss of ten minutes for every period of induction means a serious leakage of time when six or eight operations have to be performed in an afternoon.

[1] Revue de Chirurgie, January and February, 1906.

WELL DESERVED HONOURS.

THE University of Oxford at a Convocation held on May 28th conferred the honorary degree of M.D. upon Mr. Wilfred Thomason Grenfell, L.R.C.P. Lond., M.R.C.S. Eng. The honour was given in recognition of the good work carried out among the fisherfolk of Labrador under Dr. Grenfell's supervision. Dr. Grenfell, who was educated at Queen's College, Oxford, and at the London Hospital, qualified in 1888 and joined the Royal National Mission to Deep Sea Fishermen in 1889. At first he worked on board the mission vessels in the North Sea but in 1892 he initiated work of a similar kind among the fishermen in Labrador where, having obtained his certificate as a master mariner, he commanded his own vessel. In Labrador and Newfoundland he has helped in establishing four hospitals, besides various coöperative stores and other institutions for the good of the inhabitants. Sundry most interesting articles from his pen have recently appeared in the columns of our contemporary the *Standard*, which give a vivid account of the hardships of a medical missionary, as well as of the benefits which his skill and knowledge can confer. We congratulate Dr. Grenfell upon the compliment paid to him by his University—a compliment which is all the more noteworthy inasmuch as it is the first occasion upon which the honorary degree of Doctor of Medicine has been conferred. On May 31st Dr. Grenfell was the recipient of another honour, for he was invested by His Majesty the King with the insignia of a Companion of the Most Distinguished Order of St. Michael and St. George.

WIDAL'S REACTION IN JAUNDICE.

SOON after the discovery of the Widal reaction in typhoid fever it was noticed that the serum of certain persons not suffering from the disease agglutinated typhoid bacilli. This was observed particularly in jaundice. But in most cases a reaction was obtained only in low dilutions and after long periods (from two to eight hours). Judged by the usual standards of the present time such reactions would not be regarded as positive and as any evidence in favour of the diagnosis of typhoid fever. But there remains a small group of cases of jaundice in which the serum possesses high agglutinative properties. In the *Boston Medical and Surgical Journal* of April 25th Dr. H. A. Christian has contributed an important paper on the subject. He reports the following case. A man, aged 42 years, was admitted into hospital on Nov. 6th, 1906. Five weeks before he was awakened from sleep by severe pain in the right hypochondrium. Frequent attacks of pain followed and jaundice, with clay-coloured stools and dark urine, developed. On admission there were deep jaundice and marked tenderness and slight rigidity and spasm in the region of the gall-bladder. The patient had suffered from typhoid fever seven years previously. The blood serum agglutinated the typhoid bacillus in a dilution of 1 in 50 in 20 minutes. On the 10th choledochotomy was performed and a stone was removed from the common duct. The patient did well for a time but gradually failed and died on Dec. 9th. The stone was two centimetres in diameter, slightly irregular, semi-translucent, and crystalline. Cultures made from the almost colourless fluid in the gall-bladder and from the centre of the stone showed the typhoid bacillus. At the necropsy no typhoid lesions were found in the intestine. The gall-bladder was contracted and thickened. The bile-ducts seemed normal and contained no calculi. A positive agglutinative reaction in jaundice may be explained as due to the action of biliary substances dissolved in the serum. But there is much evidence against this view. The reaction cannot be obtained in many cases in which the jaundice is deeper than in those in which the reaction is present. Normal serum to which bile has been added does not give the reaction. Analysis of the reported cases of jaundice with an agglutinative reaction as high as a dilution of 1 in 50 in 30 minutes shows that they be divided into several classes: (1) those with a history of an attack of typhoid fever; (2) those in which typhoid bacilli are found in the biliary tract; (3) those in which there is acute infectious jaundice; and (4) those not belonging to any of the preceding classes. The fact that the agglutination reaction persists for some time after typhoid fever explains the first class. When the fever much antedates the jaundice the inference is that the bacillus persists in the system. The case recorded above is an example. A case has been recorded by Droba in which the bacillus was isolated from the gall-bladder 17 years after an attack of typhoid fever. With regard to the second class, several cases of cholelithiasis have been reported with no history of typhoid fever in which the typhoid bacillus has been found in the biliary tract. The third class includes the condition known as "Weil's disease" and others which may be examples of atypical typhoid fever. With regard to the fourth class, it has been shown that even in the absence of a history of typhoid fever a person may harbour the typhoid bacillus. The reason for the frequent association of jaundice with the agglutinating reaction is the fact that the gall-bladder is a site of election of the typhoid bacillus which often persists there long after an attack of typhoid fever, possibly producing cholecystitis and cholelithiasis.

THE BICENTENARY OF LINNÆUS.

THE bicentenary of Linnæus, celebrated by the Royal University of Upsala on May 23rd (May 13th, O.S.), has been the occasion of some graceful tributes to the memory of the great Swedish naturalist. Notable among these are the addresses forwarded to Upsala by the trustees of the British Museum and the director of the British Museum of Natural History. Professor Edwin Ray Lankester makes a happy allusion in the opening sentences of his address to the visit of Linnæus to this country in 1736. "There is preserved in the British Museum a letter from the celebrated Boerhaave introducing to our founder, Sir Hans Sloane, a young Swedish friend. 'Linnæus,' the letter runs, 'Linnæus qui has tibi dabit literas est unice dignus a te videri; qui vos videbit simul, videbit hominum par, cui simile vix dabit orbis.'" Despite this excessive compliment, or because of it, Sloane is said to have given the young man of genius a cold reception, little divining what a valuable connexion would in future exist between the learned of England and of Sweden. "Upon the material foundation of Sloane," to quote the address further, "have arisen the vast collections of the British Museum; from the genius of Linnæus have branched out the sciences of descriptive botany and zoology, enabling us to reduce to order these ever-growing collections. And throughout this growth there have ever been conspicuous the cordial intercourse and mutual aid between the naturalists of our two countries, initiated when Linnæus visited this 'punctum saliens in vitello orbis.'"

it in the same number of THE LANCET by our Paris correspondent. Dr. Bouchard of Limoges reports four cases of irido-keratitis in women with irregular menstruation which cleared up only when the menstrual functions became normal. We have recently referred to the same matter in our review of Berger and Loewy's Diseases of the Eye of Sexual Origin in Women.[3] The association of irido-cyclitis with pyorrhœa alveolaris must be regarded as beyond dispute and is explained with greatest probability on the theory of the elimination of toxins with the intraocular lymph by the ciliary processes. If this be true it is likely that toxins of other origin are similarly excreted and in the absence of oral sepsis and disorders of the generative system the most probable site is the gastro-intestinal tract. We are not aware that any observations upon the opsonic reactions of patients with irido-cyclitis have yet been carried out. It is not unlikely that a subnormal index for bacterium coli might be found in some of these cases.

EPIDEMIC CEREBRO-SPINAL FEVER.

STATISTICS recently published by the medical officer of health of Glasgow show that in that city up to March 31st there had been a total of 312 cases of epidemic cerebro-spinal fever treated in hospital to a termination, and that among them there had been 230 deaths, giving a death-rate of 73·7 per cent. Of the total number of cases, 175 were verified bacterially, and the deaths numbered 145, a rate of 82·9 per cent.; 137 were not bacterially verified, but on clinical grounds were regarded as cerebro-spinal fever, and of these 85 died, giving a rate of 62·0 per cent. The outbreak consisted mostly of single cases in separate households distributed over a wide area. It occurred chiefly in children who were related to each other with regard to the date of sickening but had, as a rule, no common centre of infection which was discoverable. Discussing possibilities of infection he suggests that the prevalent habit of kissing children may be one method by which the organism is transferred to them from "carrier" cases. In Scotland during the week ended June 1st there were 17 deaths from this cause registered in Glasgow, two in Leith, and one in Edinburgh. In Glasgow the weekly report issued on May 31st showed that there were at that time 110 cases under treatment. In the quarterly summary of the births and deaths in the principal urban districts in Ireland special tables dealing with this subject have been inserted. During the 13 weeks ended Saturday, March 30th, there were 13 deaths from this cause recorded in the Dublin registration area. In Belfast during the same period 233 cases were notified and there were 154 deaths, 90 of males and 64 of females, deaths of persons admitted from without the county borough being excluded. The first of the 13 weeks of the quarter ended on Saturday, Jan. 5th; the progress of the epidemic in Belfast is marked by the number of deaths during each of these weeks, the successive numbers being two, one, one, two, 12, 14, 12, 12, 22, 22, 19, 14, and 21. The deaths at various ages were as follows: under one year, 12 males and seven females; one year and under five years, 33 males and 12 females; five years and under 20, 34 males and 37 females; 20 years and under 40, 14 males and four females; and 40 years and under 60, one male. Almost all the deceased belonged to the labouring, artisan, or lower middle classes; one was the infant child of a "medical doctor," one was a medical student, and one was a school teacher. As regards duration of the illness, 117 of the 154 patients died in less than seven days, the periods being as follows: under 24 hours, 35 cases; one day, 24 cases; two days, ten cases; three days, 19 cases; four days, eight cases; five days, 13 cases; and six days, eight cases. In Belfast during the week ended June 1st 14 deaths were registered.

EPSOM COLLEGE.

A COPY of the voting paper for the election of pensioners and foundation scholars in connexion with the Epsom College Foundation has reached us, and we notice with regret that the percentage of cases where the husband or father of the candidate has supported the institution in his better days is still very small. In but two instances out of the 16 applications for pensionerships has such support been given and in only seven out of the 33 applications for foundation scholarships; we note that four of these are recommended by the selection committee as being in its opinion the most urgent cases. Another point worthy of attention is the fact that candidates reside in various parts of the British Isles. At times the foundation is referred to as a "South of England charity" by those who are not familiar with the scope of its work, and the addresses of candidates on this voting paper are the best refutation of such a statement. There are several applicants in Scotland, Ireland, Yorkshire, and Lancashire—in fact, quite one-fourth of the candidates are from these four distant centres. It is unfortunate that whilst there are only seven vacancies for foundation scholarships there are no fewer than nine applicants who cannot again stand as candidates owing to age, but since the maintenance of these scholarships depends almost entirely upon the receipts from annual subscriptions and donations the profession is to blame that the number available is not greater. If every medical man were to contribute half a guinea annually the numbers of pensions and scholarships could be materially increased, if not actually doubled, and it is difficult to imagine that there are many who could not afford to send this sum every year, which works out at about 2½*d.* a week. The working classes set a good example in making provision for old age and for days of trouble; it is a pity that medical men show less forethought and too frequently leave widows and orphans to face the heart-breaking trials of poverty. When it is recollected that there are over 30,000 members of the profession and that the total amount received by the college in annual subscriptions from all sources is under £4000, it can hardly be said that generous support is given to the foundation attached to the college which provides for pensions of £30 a year to 50 medical men or their widows and educates, clothes, and maintains free of charge 50 scholars, the sons of medical men.

THE TUBERCULOSIS PROBLEM IN SOUTH AFRICA.

AN important conference was held at the beginning of May in Capetown between the mayors and the medical officers of municipalities in the Cape Peninsula to consider the steps to be taken for the prevention of pulmonary tuberculosis. One of the speakers stated that 20 years ago the life insurance companies, relying on the excellence of the climate, did not take much notice of the disease when considering a proposal for a policy, but that now, in consequence of the enormous spread of consumption during the last few years, it was reckoned, as in England, one of the chief factors against which they must guard themselves. There was abundant medical testimony as to the great spread of the disease throughout the white and the black populations, and the chief danger was ascribed to lack of hygienic precautions in dealing with the later cases of the disease, especially amongst the natives who are very much afraid of hospital treatment and herd in small rooms in such a way as to produce a great number of cases by direct infection. It was felt that the compulsory removal of advanced cases to special more resistant to the gastric juice, no doubt because it is accustomed to it. The morbid anatomy of these ulcers is the same as that of peptic ulcer of the stomach or duodenum; they are almost always single. The symptoms resemble those of the gastric ulcer. There may be none until perforation takes place; this occurred in eight of the 31 cases. In 20 of the remaining cases there were signs of adhesive peritonitis—the anterior abdominal wall was infiltrated and an indistinct mass was felt.

---

[3] THE LANCET, April 27th, 1907, p. 1166.

THE COMPULSORY RETIREMENT OF POSTAL MEDICAL OFFICERS UNDER AN AGE LIMIT.

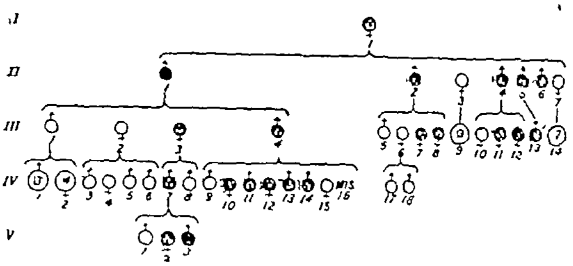
WE are informed that the Postmaster-General has intimated to the Association of British Postal Medical Officers that he "recognises that on the first introduction of a new practice as regards medical officers over 70 some inconvenience may have been caused in particular cases, and if there are instances in which hardship could be shown and at the same time the officer is fully efficient Mr. Buxton would be prepared to consider whether the date of retirement might be postponed for a time." Any postal medical officer desirous of availing himself of this offer would do well to communicate immediately with Dr. R. R Giddings, 206, Mansfield-road, Nottingham, the honorary general secretary of the Association of British Postal Medical Officers.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual election of members of Council of the College will be held on Thursday, July 4th next, at 3 P.M. There will be four vacancies caused by the retirement in rotation of Sir John Tweedy, Mr. Herbert William Page, Mr. Charles William Mansell Moullin, and Mr. Frederic Samuel Eve. We understand that Sir John Tweedy does not intend to offer himself for re-election, but the three other retiring members will again become candidates. The names of several other Fellows have been mentioned as likely to be candidates, among others those of Mr. W. Bruce Clarke, Mr. Charles Higgens, Mr. Charters J. Symonds, and Mr. W. Dunnett Spanton (Hanley), but we hope to give the complete list next week. All nominations must reach the secretary by Monday, June 10th, at the latest. It will be noticed that the hour of meeting has been put later than on previous occasions; this has been done to facilitate the attendance of Fellows, six of whom unconnected with the Council must be present before the commencement of the proceedings. Personal attendance, however, is not essential for the exercise of the privilege of voting, for a voting paper will be sent to every Fellow in the United Kingdom whose address is known to the secretary.

HEREDITARY MAL-DEVELOPMENT OF ENAMEL.

A VALUABLE series of cases illustrating hereditary mal-development of enamel is recorded in the March issue of the Transactions of the Odontological Society. The defect consisted in a stunted development of certain teeth accompanied by a deficiency in the amount of the enamel, the number of teeth affected varying in different members of the family. In all the cases the earlier formed teeth suffered most—namely, the incisors and the first molars, and following these the canines, premolars, and second molars in the order named. In all the cases the third molars, when present, showed a full covering of enamel. On the lower incisors no enamel was found in any case, but some of the upper incisors showed a narrow ring of enamel at the alveolar edge. The eruption and order of succession of the teeth showed no marked irregularity and no trace of tubercle, syphilis, or gout was found, all members of the family being well formed and strong. Lesions of the eye, skin, nails, and hair were absent with the exception of one male, whose vision was corrected with + 1 D. sph. Mr. J. G. Turner was unable to find any explanation of the condition, the lesion, he considered, being a want of energy which allowed cell production to proceed but which inhibited the actual enamel formation and so limited the growth of the enamel organ. An analysis of the particulars given showed that every member married an unaffected stranger and that the defect was transmitted only by abnormals, never by normals, five separate families showing this latter point; males and females were affected, the proportion of abnormals to normals being nearly 2 to 1. The series is interesting to those engaged in the study of heredity and disease. The pedigree of the family is as follows:—



● indicates an affected person.
○ indicates an unaffected person.

A large circle with a number inside indicates a child; where sex is known it is added.

THE BACTERICIDAL PROPERTIES OF TEARS.

OUR Copenhagen correspondent has recently[1] drawn attention to a work by Dr. O. Lindahl on the bactericidal properties of tears. The subject is one which has been submitted to a considerable amount of investigation with contradictory results. Dr. Lindahl finds that the bactericidal properties are abolished by heat and are hence attributable not to the inorganic constituents of the fluid but to organic constituents and leucocytes. Such a view is *a priori* the more probable but the diametrically opposite results obtained by Bach have to be taken into consideration. Bernheim, Marthen, and others agree that the lacrymal secretion has a deleterious effect upon the growth of staphylococcus aureus but Ahlstroem, de Bono and Frisco, and others failed to confirm this result. Helleberg found that the slight effect observed with staphylococcus aureus was abolished by heating to 58° C. and attributed it to alexins. Van Genderen failed to find any bactericidal effect with bacterium coli, and de Bono and Frisco with typhoid, cholera, and diphtheria bacilli, though the virulence of staphylococcus aureus and the diphtheria bacillus was diminished. Römer found that anthrax bacilli kept for eight days in the conjunctival sac, the lids having been sewn together, were still living and virulent. It will be seen, therefore, that the evidence is conflicting and we are only justified at present in asserting that the lacrymal secretion is a bad culture medium for bacteria. A cognate question which has received some attention is the presence or absence of the products of immunisation in tears. Here, again, the evidence is conflicting, though generally in the negative. As regards diphtheria antitoxin, Gosetti and Jona and de Bono and Frisco obtained positive results but these were not confirmed by the researches of Coppez and Demaria. Rymowicz failed to find agglutinins in the tears of dogs immunised against typhoid fever and cholera but Schulz, Dieulafoy, Widal, and Siccard obtained a positive Widal reaction in typhoid fever patients. Another problem nearly allied to the foregoing is the question of the elimination of toxins by the ocular fluids and attention has been drawn to reaction). The same medium in Petri plates is also of service for the subculture by means of parallel stroke inoculations of all Gram-negative cocci which may be found in the primary culture. In these subcultures there is usually such a marked differentiation of the species that the meningococcus, if present, can be selected at once for further diagnostic tests by means of four serum tubes, each containing one of the four sugars recommended by Gordon—namely, glucose, galactose, maltose, saccharose. With 18 hours' incubation the meningococcus shows an acid reaction in glucose, maltose, and galactose. The reaction in the glucose tube is further distinguished in the case of the meningococcus by the production of fluorescence in the water of condensation and by the formation of a yellow deposit of the growth which, as seen through the glass, has often the appearance of pus. This reaction has not been observed in connexion with any other Gram-negative diplococcus. In the galactose tube the reaction is not nearly so pronounced, the growth never appearing more than faintly acid, while in the saccharose tube growth takes place without any apparent change in the medium.

---

[1] THE LANCET, May 25th, 1907, p. 1463.

This method, together with the temperature tests (i e., failure of the meningococcus to grow at 23° to 25° C.) affords a very rapid means of isolating the meningococcus. It has the further advantage also that the same medium is suitable for all the tests, for it has been found that a considerable loss of vitality is apt to be incurred in transferring the growth from one kind of medium to another. It may be added that the organism retains its vitality on this medium in capped tubes for at least a fortnight when kept in the incubator.

Public Health Laboratory, Glasgow.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 6th, 1829.

FOREIGN DEPARTMENT.

LITHOTRITIC OPERATION.

M. DUBOIS, the Nestor of French surgery, was lately in a very precarious state of health, so that for a long time his recovery, and even his life, was despaired of. The disease under which he laboured, was stone in the bladder, and we are happy to inform our readers, that it has ultimately been successfully removed by M. Civiale's method, in justice to whom we subjoin the following letter of M. Dubois to the editor of the *Gazette de Santé*:—

"Sir, allow me to acknowledge, by the channel of your journal, the obligations which I feel to my colleagues, for the lively interest they have shown towards me, during my late illness, from which, by the skill of my friend M. Civiale, I have eventually been freed, so that my health is rapidly recovering. I feel proud to be able to add something to the recommendation of M. Civiale's method, which is an effectual substitute for one of the most painful and dangerous operations in surgery, and the invention of which renders his name worthy of a place in the list of the benefactors of mankind.

"I have the honour to be, &c.

"A. DUBOIS."

"4th of May, 1829."

ITALIAN RED CROSS SOCIETY.—The *Official Gazette* of Italy contains a report of the annual meeting of the Italian Red Cross Society held at Rome on May 20th. In his presidential address Count Taverna referred to the society's work in the anti-malarial campaign in the Roman agro and pontine marshes districts and to its exceptional work in dealing with accidents caused by the eruptions, &c., in Calabria and the surroundings of Vesuvius. Special votes of thanks were passed to Professor Postempski for his administration of the anti-malarial campaign and to the president. The new council was elected as follows: Professor Commendatore Gaetono Mazzoni, Professor Bonaldo Stringher (Grand Cordon Cross of Italy), General Doctor Francesco Randone, Commendatore Filippo Geneovesi, and Avvocato Giovanni Ciraolo.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, MAY 29TH.

THE sittings of the Council were resumed at their offices in Oxford-street on Wednesday afternoon, May 29th. Dr. DONALD MACALISTER, the President, again occupied the chair.

Penal Cases.

The Council took up the consideration of penal cases.

The first case was that of George Covey, registered as of 1, Heathcote-street, Mecklenburgh-square, London, W.C., Mem. R. Coll. Surg. Eng. 1864, Lic. Soc. Apoth. Lond. 1865, who had been summoned to appear before the Council on the charge that he was, on April 23rd, 1907, convicted of the following misdemeanours at the North London sessions—namely, of obtaining money by false pretences and of obtaining money by fraud while being an undischarged bankrupt.

The SOLICITOR (Mr. Winterbotham) read the charge and put in a certificate of the conviction.

Mr. Covey did not appear, nor was he represented. However, a letter was read from him expressing his sincere regret for the position in which he stood. He stated that he had been 40 years in the profession and no professional complaint had ever been brought against him.

After consideration of the case *in camerâ*,

The PRESIDENT said: I have to announce that the decision of the Council is that George Covey, having been proved to have been convicted of various misdemeanours, the Registrar has been directed to erase his name from the Medical Register.

The Council then considered the case of Andrew Dunn Turner, registered as of 71, Marina, St. Leonards-on-Sea, M.B., Mast. Surg., 1882, Univ. Glasg., who had been summoned to appear before the Council on the charge that he was on Nov. 21st, 1906, convicted of the following misdemeanour at Lewes assizes—namely, of unlawfully, maliciously, and scandalously writing and publishing an obscene letter at Hastings on June 25th, 1906.

The SOLICITOR handed in the certificate of conviction. Mr. TURNER appeared in person but did not address the Council. A letter, however, was read from him in which he expressed the hope that the Council would be lenient with him for his wife's sake.

The Council having considered the case *in camerâ*,

The PRESIDENT announced its decision. He said: Mr. Turner, I have to inform you that, having been proved to be guilty of a misdemeanour, the Registrar has been directed to erase your name from the Medical Register.

The next case that came up for consideration was that of Edward John Havens, registered as of East Donyland, Colchester, Mem. R. Coll. Surg. Eng. 1879, Lic. Soc. Apoth. Lond. 1879, who had been summoned to appear before the Council on the charge that he was on Nov. 5th, 1906, convicted of the following misdemeanour at Thorpe petty session, Thorpe-le-Soken, Essex—namely, of obstructing the highway; also that he was on Dec. 17th, 1906, convicted at the like session of disorderly behaviour whilst drunk; and also that he was on April 8th, 1907, convicted of the following misdemeanour at Mistley petty session—namely, of common assault.

Mr. HAVENS appeared in person. After the charge had been read and various reports with regard to it submitted Mr. Havens shortly addressed the Council. He mentioned that he had not practised for ten or 12 years.

The PRESIDENT, after the Council had deliberated *in camerâ*, announced its decision in the following terms: Mr. Havens, the Council having considered the case proved against you, adjourn the further consideration of the question until the November session, when you will be asked to appear again before the Council to hear the final result of their deliberation.

The Council then considered the case of James Marston. It was reported to the Council by the Dental Committee that the following facts were established by the evidence:—

(a) The said James Marston is on the Dentists' Register as in practice before July 22nd, 1878, and of the address: The Shrubbery, East Howe, Kinson, Bournemouth.

(b) The said James Marston was convicted of bigamy on Jan. 15th, houses or hospitals should be enforced at once, and in resolutions adopted by the conference the Cape Government was invited to provide such accommodation, to complete the Alexandra Hospital at Maitland which is to have special wards devoted to cases of tuberculosis, and further to appoint a commission to inquire into, and to report upon, the best means of dealing with consumption. A deputation of mayors was appointed to wait on the Government to present these resolutions, copies of which were also furnished to the members of the legislature representing the Cape division. Support for the scheme has been promised by some of the Members of Parliament but there seems to be a general feeling that the funds at the disposal of the Government will not permit of an efficient scientific commission being appointed; it is suggested that a Government inquiry might serve instead. The whole matter is to be brought up in the Parliament of the colony and it is to be hoped that no dilatory or cheese-paring policy will be adopted, for there is no doubt that the soundest economy will be in tackling the problem in a systematic and energetic manner before it has reached such well-nigh overwhelming proportions as is unfortunately the case in the countries of Europe.

INVITATION cards in connexion with the National League for Physical Education and Improvement have been issued for the Duchess of Devonshire's "At Home" at Devonshire House, Piccadilly, London, W., on June 11th, from 3.30 to 6 P.M. The Duke of Devonshire, K.G., will preside at the reception. Those announced to speak are the Lord Chief Justice, Sir Gilbert Parker, M.P., and the Lord Bishop of Ripon. Communications should be addressed to the Secretary, National League for Physical Education, Denison House, Westminster. At the reception those members of the league who wear a knot of ribbon will be pleased to answer questions and to give information to any who may desire it.

THE Home Secretary has issued an Order (Statutory Rules and Orders, 1907, No. 407) extending the provisions of Section 8 of the Workmen's Compensation Act, 1906, to a number of other industrial diseases and injuries. The schedule of diseases and injuries, 18 in number, was drawn up by a committee appointed by the Home Secretary to inquire into the matter. This committee recently issued a report of its deliberations with which we dealt in a leading article published in our issue of June 1st.

AN endeavour is being made to arrange an annual dinner of past and present members of the West African Medical Staff. It is hoped to hold the inaugural dinner in the first week of July. Members of this service who are at present on leave and who have not yet received any communication on the subject are requested to communicate with Dr. W. T. Prout, late principal medical officer, Sierra Leone, as early as possible, at 17, Canning-street, Liverpool.

THE annual Bolingbroke lecture of the South-West London Medical Society will be delivered on Wednesday evening next, June 12th, at 9 P.M., at the headquarters of the 4th Volunteer Battalion East Surrey Regiment (opposite Clapham Junction station). Dr. G. H. Savage is the lecturer and has chosen for his subject the Factors of Insanity. Medical men, whether residing in the district or not, are cordially invited to be present.

THE medical officer of health of the Cape Colony states that for the week ending May 11th 2 cases of plague in man were discovered, 1 on May 5th in a European girl and 1 on May 8th in a native male adult. Both patients resided at King William's Town. The Department of Public Health of Queensland, in a bulletin dated April 27th, states that for the week ending on that date no case of plague occurred in Brisbane.

THE annual general meeting of the Medical Officers of Schools Association will be held on Thursday next, June 13th, at 3.45 P.M., at 11, Chandos-street, Cavendish-square, W., when it will be proposed that members of the scholastic profession shall be eligible for election as associate members. This is an excellent proposal and we hope that it will recommend itself as such to the members.

AT the meeting of the corporation of the City of London held on May 30th it was decided to present the honorary freedom of the City to Lord Lister and to the Earl of Cromer. It is over 100 years since the freedom of the City was bestowed upon a member of the medical profession, the last of our *confrères* so honoured being Edward Jenner.

ON THE DIFFERENTIATION OF THE MENINGOCOCCUS FROM OTHER GRAM-NEGATIVE DIPLOCOCCI IN THE NASOPHARYNX OF CEREBRO-SPINAL FEVER CONTACTS.

BY R. M. BUCHANAN, M.B. GLASG., F.F.P.S. GLASG.,
BACTERIOLOGIST TO THE CORPORATION OF GLASGOW.

THE very considerable number of Gram-negative diplococci met with in the naso-pharyngeal secretion of persons who have been in contact with cases of cerebro-spinal fever has stimulated the desire for some method by which these organisms might be accurately and rapidly differentiated. In the course of the epidemic of cerebro-spinal meningitis in Upper Silesia in the winter of 1904–05 von Lingelsheim[1] isolated seven Gram-negative cocci from the naso-pharynx and was aided in their identification by the presence or absence of ability to decompose certain sugars. These sugars were glucose, lævulose, galactose, mannite, dulcite, saccharose, maltose, lactose, and inulin. The medium on which he tested the action of a given coccus on a given sugar was plated ascitic agar with litmus as indicator. An acid reaction was produced by the meningococcus in 24 hours at 37° C. in glucose and maltose only, while by contrast the micrococcus catarrhalis for example produced no change in the whole series of sugars.

In 1905 Dr. M. H. Gordon[2] pointed out that glucose, galactose, maltose, and saccharose in a fluid medium tinted with litmus had a special application for the purpose of differentiating Gram-negative cocci, and in his recent report to the Local Government Board "On the Micrococcus of Epidemic Cerebro-spinal Meningitis and its Identification" he demonstrates the value of this differential method, with special reference to the meningococcus. The question of acid production was observed during incubation aerobically at 37° C. for a week, when it was found that acid production took place also in galactose. The time required for the production of the acid reaction in the fluid media (from 48 hours to seven days) is undoubtedly a drawback to this valuable differential test.

In the course of extended trials of various nutrient media for the cultivation of the meningococcus in this laboratory it has been found that ox serum after Löffler's formula (three parts ox serum, one part bouillon, and 1 per cent. glucose) gave the best results. Accordingly, to this medium neutral-red in the proportion of 1 to 10,000 was added as indicator. On this medium the meningococcus grows rapidly and profusely, and the neutral-red causes the growth to assume a pink tint. For primary cultures from the naso-pharynx Petri plates are used, and the resulting mixed growth generally shows a number of organisms capable of acid production. There may be one or two species indistinguishable with the naked eye from the meningococcus, but, on the other hand, the medium renders great service in at once differentiating between meningococcus and micrococcus catarrhalis (the latter producing no

[2] Dunn and Gordon: Brit. Med. Jour., August 25th.

Council should be made clear before they did anything more.

Sir T. **McCall Anderson** seconded the motion.

The motion was agreed to.

Dr. **Saundby** then moved that the report should be formally approved of.

Sir **John W. Moore** seconded.

The motion was unanimously agreed to.

Students' Practical Midwifery Committee.

The reports by the Students' Practical Midwifery Committee as to the inclusion of clinical and practical work in the qualifying examinations in midwifery and gynæcology and also as to the further communications sent by the licensing bodies and teaching institutions of the United Kingdom were received.

The consideration of the recommendations in those reports was deferred until the following day.

The Council at this point adjourned until Thursday.

THURSDAY, MAY 30TH.

The Council resumed its sittings to-day at its offices at 299, Oxford-street. Dr. **Donald MacAlister**, the President, was again in the chair.

Instruction in Midwifery.

Sir **John Williams** moved the adoption of a series of recommendations which, the Students Practical Midwifery Committee submitted, should be substituted for the existing recommendations of the Council in regard to instruction in midwifery.

The first recommendation of which Sir **John Williams** moved the adoption was in the following terms :—

> Every student before commencing the study of practical midwifery shall be required to have held the offices of clinical medical clerk and surgical dresser and to have attended a course of lectures on surgery and midwifery.

He said that in submitting a series of recommendations from the committee on the teaching and practice of midwifery, it was not necessary for him to enter into the reasons why they had come to the conclusions contained in them. Communications had been sent by the committee to the licensing bodies and teaching institutions of the United Kingdom containing a request for their observations on the committee's first report which was received by the General Medical Council on May 28th, 1906. This report was sent to the 27 licensing bodies and the answers which had been received were considered by the committee.

Mr. **Young** formally seconded the motion for the adoption of the recommendation.

Sir **Thomas Fraser** thought that the Council should have good reasons from the committee why it put forward the recommendation in this particular form.

Dr. **Finlay** pointed out that the adoption of any provisions beyond what were really necessary was likely to lead to difficulty.

Sir **John Moore** then moved as an amendment that the word "medicine" should be inserted before the word "surgery" so that it should be set out in the recommendation that every student should have attended "a course of lectures on medicine, surgery, and midwifery."

Dr. **Pye-Smith** seconded the amendment.

Dr. **Saundby** did not see that the amendment would make any serious difference as the recommendation would, without it, provide that every student before commencing the study of practical midwifery should be required to have held the office of clinical medical clerk.

Dr. **McVail** explained the reasons which had influenced the committee in not including the word "medicine." The reports of some of the most important licensing bodies showed that it was useless to make the recommendation as to medicine, and it was undesirable for the General Medical Council to make important recommendations which the most important bodies would not adopt. It was for that reason that the members of the committee—some of them with great regret—cut out the lectures on medicine. Many of the members of the committee thought that medicine should be included, but from the replies they got they saw it was hopeless to get any observance of a rule if they made it. They got a consensus of opinion in favour of including surgery.

Dr. **Lindsay Steven** considered it would be wrong to make any regulation whereby a man should be a clinical clerk before he had received any systematic instruction in medicine. He felt inclined to support Sir John Moore's proposition.

Sir **John Moore**, in replying to the discussion on his amendment, emphasised his view that it was desirable that a man entering on a course of practical midwifery should have a good knowledge of practical and systematic medicine and surgery.

The amendment was declared to be lost after a show of hands had been taken.

Sir **John Moore** then moved another amendment that the words "surgery and" should be omitted from the recommendation.

Sir T. **McCall Anderson** seconded the amendment. He considered that it was unnecessary to bring in this reference to surgery. A clinical medical clerk was a senior student, as was also a surgical dresser.

Dr. **Norman Moore** supported the amendment. To put these lectures into the recommendation would be a most unnecessary obstacle to the student in arranging his work.

Mr. **Morris** said that it was very certain that if they insisted on these students being clinical medical clerks and surgical dressers they would have attended lectures.

The amendment was defeated by 16 votes to 13.

Dr. **Mackay** moved as a further amendment that the following provision should be substituted for the recommendation as moved by Sir John Williams :—

> That every student before commencing the study of practical midwifery shall be required to have attended a course of clinical instruction in medicine, and to have held the office of surgical dresser, and to have attended a course of lectures on surgery and midwifery.

Dr. **Finlay** seconded the amendment.

Dr. **Caton** remarked that the committee believed that in framing its recommendation it had outlined a reform which would make the study and practice of midwifery much more serious and much more practical in the future than it had been in the past.

Sir **John Williams** mentioned that a large majority of the licensing bodies were in favour of having the provision as to medical clerks and surgical dressers as the committee had set it out.

The amendment was lost on a show of hands.

The recommendation proposed by Sir **John Williams** was then adopted *nemine contradicente.*

Sir **John Williams** then moved the adoption of the following recommendation :—

> Every student shall be required either
>
> (*a*) To have regularly attended the indoor practice of a lying-in hospital or the lying-in wards of a general hospital for a period of three months; and after having received therein practical instruction in the conduct of labour, under the personal supervision of a medical officer, to have conducted 20 cases of labour under official medical supervision; or
>
> (*b*) To have conducted not less than 20 cases of labour, subject to the following conditions—
>
> That he has, during one month, given regular daily attendance upon the indoor practice of a lying-in hospital or the lying-in wards of a general hospital; and that he has therein conducted cases of labour under the personal supervision of a medical officer of the hospital, who shall, when satisfied of the student's competence, authorise him to conduct outdoor cases under official medical supervision.

Mr. **Young** seconded the motion.

Mr. **Morris** remarked that such a provision would throw difficulties in the way of London students owing to lack of opportunities they would experience in obtaining the midwifery cases.

Dr. **Langley Browne** moved as an amendment to insert in Clause (*b*) after the words "general hospital," "or of a Poor-law infirmary having a resident medical officer recognised for that purpose by any of the licensing bodies." Some of these Poor-law infirmaries, he said, would be as good as lying-in hospitals in providing the necessary midwifery experience for students, and he did not see why the opportunities which they afforded should not be utilised.

Dr. **Lindsay Steven** seconded the amendment.

Sir **Charles Ball** commented on the provision in the recommendation that the student should be required "to have conducted 20 cases of labour." If by "conducting" it was meant that one case of labour would only be attended by one student it would be impossible for every student to get cases. It seemed to him that it was an impossible thing to require that each student should have the personal conduct of 20 cases. He could not, therefore, see how this recommendation could be carried out.

Sir **Thomas Fraser**, speaking from the experience on this point in Edinburgh, thought that the committee had fixed the number of cases much too high. The same purpose would be served by eight or ten cases.

1906, at the Dorset assizes and was sentenced to 12 months' imprisonment with hard labour.

Mr. Marston did not appear nor was he represented.

After consideration of the case *in camerâ*,

The PRESIDENT said: I have now to announce that James Marston, having been proved guilty of a felony, the Registrar has been directed to erase his name from the Dentists' Register.

The next case considered was that of Thomas William Frederick Stewart. The complaint against Mr. Stewart having been referred to the Dental Committee, he appeared before it on May 27th, 1907, and was duly heard. The Committee found that Mr. Stewart was on Nov. 21st, 1906, convicted at Lewes assizes of feloniously embezzling the several sums of 10*s.* on July 15th, £1 8*s.* on Sept. 23rd, and £5 5*s.* on Oct. 7th, 1906, moneys of Frederick Charles Proctor, his master.

This report having been read Mr. STEWART briefly addressed the Council.

The PRESIDENT, after the usual deliberation of the Council *in camerâ*, announced the decision. He said: Thomas William Frederick Stewart, I have to announce that the Council have carefully deliberated on your case and have come to the following finding: Thomas William Frederick Stewart, having been proved to have been convicted of a felony, the Registrar has been directed to erase his name from the Dentists' Register.

The Council took up consideration (adjourned from Nov. 29th, 1906) of the facts proved against William Henry Moseley and James Parkinson, whose names appear on the Dentists Register as "in practice before July 22nd, 1878," and who were connected with the company of Foley's, Limited.

A supplementary report on these cases was received from the Dental Committee in which it was stated that the committee had found that both Mr. Moseley and Mr. Parkinson had, since the hearing of the case by the Council in November last, done their best to sever their connexion with the company and they had both parted with their shares in the company, and they had respectively practised at Ipswich and at Uxbridge-road independently of the company and there was no evidence that their professional conduct in the interval had been otherwise than satisfactory.

Mr. Parkinson appeared in person but Mr. Moseley did not attend.

The PRESIDENT said that he was authorised by the Dental Committee to say that a certificate had now been received to the effect that Mr. Parkinson had entirely severed his connexion with the company by transferring his shares in it.

The PRESIDENT, after another brief deliberation with the Council *in camerâ*, said: Mr. James Parkinson, I announce to you and through you to Mr. William Henry Moseley that the Council, having further considered the charge against you and the report of the Dental Committee, have not adjudged you guilty of disgraceful or infamous conduct in a professional respect.

That concluded the consideration of the penal cases on the agenda.

The Council and the British Medical Association.

A report by the Executive Committee on a communication from the British Medical Association was received and entered on the minutes.

The report is in the following terms:—

The Executive Committee reports that at its meeting on Monday, May 27th, 1907, it considered the following communication from the British Medical Association:—

British Medical Association, Medical Secretary's Office,
429, Strand, London, W.C.;
Temporary address, 6, Catherine-street, Strand, W.C.,
April 16th, 1907.

DEAR SIR,—The annual representative meeting in July last decided that the British Medical Association should act as complainant in cases which, in the judgment of the Association, might require to be brought before the General Medical Council.

The Central Ethical Committee of the Association is the body whose duty it would be, on behalf of the Association, to consider whether a given case should be brought before the General Medical Council and prepare the case for the consideration of that Council.

The attention of the Central Ethical Committee has been drawn to certain decisions of the courts which make it clear that no member of the General Medical Council who has acted in such a position, for example, as member of council of a medical defence or protection society, could take part in the hearing by the General Medical Council of a case presented by the council of which he was a member. From one at least of the recorded cases, it would appear doubtful whether a person who was merely an ordinary member of a body, such as the Medical Defence Union, engaged in the presentation of cases on behalf of individual medical practitioners, could sit as a member of the Council in hearing a case presented by such a body.

The committee finds that a large majority of members of the General Medical Council are members of the British Medical Association, and some members of the General Medical Council are members of the central council of the British Medical Association or of central committees.

Having regard to these facts, but recognising at the same time that the position of the British Medical Association is somewhat different from that of bodies whose sole object is the defence of their own members, it appears to the committee advisable that the attention of the General Medical Council should be called to the position created by the decision of the Association to act as complainant in cases which may be thought to require the consideration of the General Medical Council, in order that the position of the various classes of members of the Association who might be concerned may be considered without reference to any particular case.

The committee conceives that some distinction might possibly be recognised at law in the position of the following different classes as regards their respective degrees of responsibility for the action of the Association in bringing individual cases before the General Medical Council:—(*a*) members of the Central Ethical Committee of the Association, which has been entrusted with the general duty of bringing cases before the General Medical Council without waiting for a specific authority in each case; (*b*) the central council, to which the Central Ethical Committee reports, and under whose direction it acts in some matters, while having a general authority in others; (*c*) members of central committees, other than the Central Ethical Committee, who are not members of the central council; (*d*) members of the annual representative meeting, a body annually elected, which appoints some members of and receives an annual report from the committee and gives general instructions to it, but would not have any direct responsibility for the presentation of a specific case; and (*e*) ordinary members of the Association, who are not directly engaged in its central administration.

In considering the position of these various classes it is suggested that regard may also be had to the wide range of objects of the Association and its large membership, extending throughout the British Empire, which may, it is submitted, be held to make the responsibility of an individual member of the Association, who is not a member of the Central Ethical Committee, merely nominal. At all events, such a member could not, it is submitted, reasonably be held to have prejudged a case of which he had no previous knowledge.

I am, yours faithfully,
E. H. KINSEY,
Chairman of the Central Ethical Committee.

Donald MacAlister, Esq., M.D., President of the General
Medical Council, 299, Oxford-street, W.

(*b*) The foregoing letter had, by direction of the President, been forwarded by the Registrar to the Council's solicitor for his remarks. The following reply, which had been received, was read to the Committee:—

1, New-court, Carey-street, Lincoln's Inn, W.C.,
April 24th, 1907.

DEAR MR. ALLEN,—In reply to your letter of the 23rd with regard to membership of the British Medical Association, I don't think anyone reading Lord Justice Fry's judgment in Leeson's case, pages 63 to 58 of the Cases, could say that it is at all desirable that members and subscribers to the funds of the British Medical Association should sit in judgment on cases in which that body are prosecutors. Lord Justice Fry was in a minority, but both the other learned judges treated the matter as a very serious one, while coming to the conclusion that there was no sufficient proof of bias to justify them in setting aside the judgment of the Council. Lord Justice Fry held that a subscriber to an association of this kind is virtually a prosecutor, that by subscribing to the society he indicates his sympathy with the general proceedings of the body in carrying on those transactions, and that such subscribers cannot be said to be free from suspicion of bias or prejudice in the cases of prosecutions instituted by the association to which they *subscribe*.

I think Lord Justice Fry's judgment covers this case, the only difference being that *this* Association has many objects, and this is a new object which they are now undertaking, but I really don't think this makes any material difference.

As Lord Justice Fry says, it is a matter of public policy that the proceedings of the Council should not only be free from bias or prejudice of the judges, but that they should be free from the *suspicion* of bias or prejudice, and clearly the proper course is not for a member of the Council to withdraw from the decision of a case in which the B.M.A. are prosecutors but to withdraw from membership of that body.

Faithfully yours,
WM. H. WINTERBOTHAM.

H. E. Allen, Esq., *Registrar*, 299, Oxford-street, W.

Mr. Lushington, at the request of the committee, also advised them in regard to the legal aspects of the question raised by the action of the British Medical Association.

It was resolved—

"That the Executive Committee, being advised that no member of the British Medical Association should act as a member of the Penal Cases Committee or take part in adjudicating as a member of the Council in cases in which the British Medical Association or any branch of it acts as complainants, are unanimously of opinion that it is under the circumstances undesirable that a member of the Council should during his tenure of office be a member of the British Medical Association or any other body which may submit complaints to the Council for inquiry.

May 27th, 1907. DONALD MACALISTER, Chairman."

Dr. SAUNDBY moved that the report should be sent to the general secretary of the British Medical Association for the information of that body. The letter of the chairman of the Ethical Committee, he said, seemed to be anticipating the powers which might at some future time be possibly conferred on the British Medical Association under the charter which was now being discussed and which at the present moment it did not possess. It was most desirable that the position of the British Medical Association towards this report of the Education Committee, one of the features of which was a very elaborate table of statistics referring to the ages at which students commenced study and at which they qualified, together with figures relating to the length of the curriculum actually pursued. Great care and labour had been expended by the office staff of the Council in drawing up this large table which dealt with the educational history of 1111 Licentiates and Graduates in Medicine of the year 1906. Of these, 542 qualified in England, 402 in Scotland, and 167 in Ireland. Now this table of statistics, which was presented with the report, had been divided into three great sections. There was amongst the entrants one central group containing about 80 per cent. of the whole and these commenced study at an age falling within the period of five years from 17 to 21 years inclusive. The group of those who entered earlier than 17 years of age contained about 5 per cent. of the whole, whilst the group of those who entered after 21 years of age was 15 per cent. Amongst the licentiates a similar arrangement prevailed. The central group, numbering about 80 per cent. of the whole, was composed of those who qualified within the period of seven years between 23 and 29 years of age inclusive. Those who qualified at 22 years of age or under numbered 5 per cent. of the whole. Some interesting statistics had been tabulated with regard to the mean age of the 1111 entrants, the ages above 25 being reckoned as 25. That table set forth that in the case of England the mean age was 19 years 2 months, in Scotland 19 years 3 months, and in Ireland 19 years 7 months. That gave a general mean age over all the country of 19 years 3 months. The preliminary examination was associated with students' registration, but everyone was aware that the registration of the student was a voluntary act. In anything which the Council might do with the object of improving the standard of the preliminary examination it had to be careful to carry with it the good will and support of all the licensing bodies. This question had engaged much of the attention of the Council. In 1891 more active work was begun in respect to it. In consequence of the many complaints which had been sent to the Council the matter was taken up very thoroughly and the whole system of entrance examinations was revised. In 1900 a most important step was taken and an elaborate report on the subject was undertaken by three experts appointed by the Council. He could only characterise that document as one of the most important educational documents ever drawn up in this country, because it went into the educational conditions of the time, and it showed the Council what could reasonably be demanded and the lines upon which further progress should be laid. The Council had had since that time a definite purpose and they were reaching the stage at which the senior examination should be the sole portal of entry to the medical profession. He thought that it ought to be recognised that the Council had played a most important part in the general education of the country. Now, with regard to the length of the curriculum something must be said. There were many complaints with regard to the length of the present curriculum, and the final teachers had stated that the time for their important subjects had been much encroached upon. One suggestion was to add a sixth year to the curriculum, and another was to cut out certain preliminary studies. A third suggestion was to institute a system of "blocks." Whether any one or two of these suggestions should be adopted would require considerable attention on the part of the Council, because in whatever they adopted they must enlist the sympathy of the licensing bodies. The mean length of the curriculum of the licentiates who qualified in 1906 was 6 years 11·3 months over the whole of the country. In England it was 7 years 4·9 months, in Scotland 6 years 6·2 months, and in Ireland 6 years 5·1 months. Dr. Mackay then directed the attention of the Council to certain remarks made in the concluding paragraphs of the report. The figures which were submitted in the report, it was therein stated, would afford material for a preliminary study of the questions at issue. It was important to determine whether in the present circumstances the later years of the curriculum, in the case of those who completed the course under seven years, were being encroached upon by work properly belonging to the earlier period, and whether any action was needed to insure for each or any of the groups of subjects a due proportion of the time allotted to the whole. The statistics embodied in the report threw a certain amount of light on the subject. In this connexion it became exceedingly important to know that there was a marked difference between the course pursued in Scotland and that pursued in England. They had in the case of the larger bodies in England, in the Conjoint Board and the University of London, in full operation what was known as the "block" system. That was to say, that candidates were forced to give at least two years to studies belonging to the final examination. In the case of the Scottish universities there was no such requirement and it was not unreasonable to infer that the difference between the average lengths of the curriculum as actually pursued in the two countries might be associated with this important diversity. The Education Committee now wished to apply to the licensing bodies for further particulars about those licentiates who qualified in seven years. They did not think it would be necessary in this connexion to deal with the cases of those who had spent more than eight years in the study of medicine. Such an investigation promised to yield valuable results.

Dr. NORMAN MOORE seconded the motion. After the thoroughly explanatory and lucid statement of Dr. Mackay on the report it would be unnecessary for him to make any remarks except to emphasise that this was an interim report, or, so to speak, the first volume of a collection of information which would be of great assistance to the Council.

The PRESIDENT said that he had seldom seen a body of statistics which promised to yield more fruitful results than those embodied in the report.

Dr. Mackay's motion was then unanimously agreed to.

The Finance Committee's Report.

Dr. PYE-SMITH moved the adoption of the report of the Finance Committee. That report showed that the income of the General and Branch Councils for the year ending Dec. 31st, 1906, having been £8473 14s. 2d. and the expenditure for the same period having been £8433 8s. 7d., there was a surplus of £40 5s. 7d. The Finance Committee further put on record its opinion that this result might fairly be considered satisfactory when it was remembered that the cost to the three branches of the election of Direct Representatives amounted to £870 4s. Had it not been for this expense the surplus would have been £910 9s. 7d., as against £907 18s. 8d. last year. The committee in the course of its report congratulated the Council on the expedition with which it carried out its business last year. The number of days occupied by the sessions was the same as in 1905, for though the summer session was a day longer a day was saved at the winter session. This was the only way in which any large economy could be effected and the committee desired to ask the Council to continue to bear in mind the great importance of carrying on its deliberations with business-like brevity. The committee embodied a recommendation in its report that a grant of £100, if required, should be made towards the expenses of the Irish Branch Council during the current year.

Mr. TOMES seconded the motion for the adoption of the report and it was unanimously agreed to.

The Dental Committee's Report.

The report of the Dental Education and Examination Committee was received.

Mr. TOMES moved that the application of the University of Sydney for the recognition of its degree of Bachelor of Dental Surgery should be acceded to. He said that the Dental Committee was now prepared to recommend the Council to accept this motion. At the November sittings of the Council it was agreed to defer the consideration of the application of the University of Sydney for recognition of its degree of Bachelor of Dental Surgery until further information had been received whether the general medical and surgical instruction was given at a general hospital or at a special school, and whether reciprocal recognition was given to British qualifications. The University of Sydney had informed the Registrar of the Council that the medical and surgical portions of the dental students' education were conducted at a large general hospital, and the committee reported on the information furnished that no exception could be taken to the conditions prevailing at it. They also were satisfied that reciprocity was adequately secured.

Mr. MORRIS seconded the motion, which was carried.

Mr. TOMES further moved that the following recommendation of the Dental Committee should be adopted by the Council:—

> That it be represented to the Secretary of State for the Colonies that it is desirable that recognition of foreign dental diplomas shall only be granted in the case of those countries which give reciprocal recognition to British diplomas in dental surgery.

Dr. LATIMER, as a general practitioner, expressed the opinion that the whole profession would welcome the increase in the systematic instruction on midwifery. It behoved them as a profession to have their members fully equipped in this matter. With the new departures in respect to midwives, he considered that a good deal of consultative work would occur for them and therefore they should not whittle down the number of cases to be attended.

The PRESIDENT at this point announced that two amendments besides that of Dr. Langley Browne had been handed to him bearing on the subject now under consideration. It would be for the convenience of the Council in carrying on the general discussion if their terms were announced at this stage. He would put them one by one after the discussion had terminated.

Sir CHARLES BALL intimated that he would move an amendment to the effect that in the case of the student who attended at a lying-in hospital or the lying-in wards of a general hospital for three months only ten cases of labour should be personally conducted, and in the case of the student who gave attendance for one month only 15 cases should be required.

Sir T. McCALL ANDERSON undertook to second this amendment.

Dr. SAUNDBY put forward an amendment to the effect that the Council should record its opinion that it was desirable that the provisions contained in the recommendation should only be put into operation "where the necessary hospital facilities exist." He said that he did not think it was fair to pass a resolution of this sort with the knowledge that a great many teaching bodies could not carry out its provisions. While he did not want to throw cold water upon them he thought that the Council should, at least, prefix them with such a preamble as would show that it recognised that they could not be carried out in parts of the country like Birmingham.

Mr. MORRIS was the seconder of Dr. Saundby's amendment.

Dr. McVAIL hoped that the Council would not accept any qualification of the kind put forward by Dr. Saundby. He said that there was a great scientific school of medicine at Cambridge. He wondered how Parliament would regard matters if that University said that their men need not know anything about clinical medicine or clinical surgery because they had not got the requisite opportunities of obtaining the training on the spot. Now, the question before the Council really resolved itself into this—what was the number of cases requisite for obtaining practical instruction in midwifery? He did not think any committee had ever given more attention to the matter remitted to it than had the committee which brought forward the recommendations which they were now discussing. From the information which the members had before them they came to the conclusion that a man should not be certified as being qualified in midwifery in the sense of the requirements of the Medical Act unless he had attended 20 cases of labour. If a teaching body said that it could not provide 20 cases for each student it was surely not a part of the Council's work to help in passing men into the profession who had not been sufficiently taught. If students could not get the requisite number of cases in one locality they should go elsewhere for their midwifery experience. He objected entirely to the proposals of Dr. Saundby. The Council had to insist on the students getting adequate teaching. The committee had felt that they should take some steps to secure that students should be apprised of the strides which had been made in the teaching of midwifery. 20 cases should be the minimum of the number conducted by them.

Dr. LITTLE considered that the Council should only expect what was reasonable and what could be done at medical schools, but so far as they had power the authorities of the latter should make the recommendations of the Council obligatory. He would support the amendment of Sir Charles Ball, although he thought that that gentleman underrated the facilities for midwifery in the Dublin hospitals.

Sir HUGH BEEVOR expressed sympathy with Dr. Saundby's propositions.

Sir CHRISTOPHER NIXON confirmed all that Dr. McVail had said about the time and labour given by the committee to its report. Members of the Council must remember what it was that led to the appointment of the committee to consider the instruction given in midwifery. It was appointed to deal with statements to the effect that the practice of midwifery as carried on throughout this country led to a considerable amount of mortality. This was, therefore, a question which affected the community generally and on which the general public would watch with very great interest the action taken by the Council. It was a question of human life. He did not think that the Council ought to hesitate for a moment to make a recommendation on this subject which, if not carried out now, would be carried out in the future. The recommendation of the Council should be based on what they considered necessary to prevent the loss of human life, even although it would not be possible in particular places to have it carried out at once.

Dr. KIDD, as a general practitioner, expressed agreement with the views advanced by Dr. McVail.

The PRESIDENT then proceeded to put the various amendments *seriatim* to the vote.

The amendment of Dr. Saundby was lost on a show of hands.

Dr. Langley Browne's amendment to include Poor-law infirmaries amongst the institutions where students might gain midwifery experience under the conditions of Clause (*b*) was unanimously agreed to.

Sir CHARLES BALL said that before his amendment was put to the vote he would like to make some remarks on it. It was quite possible that a student might have seen 100 midwifery cases but might not have conducted 20. He would repeat that if each case was to be conducted by one man, and one man only, then the material available in large towns was not always sufficient to provide each student with 20 cases. In asking the Council to reduce that number he would point out that under the conditions of Clause (*a*) of the proposed recommendation much more careful teaching would be given than under the conditions of Clause (*b*). That was the reason why he proposed to substitute 10 cases for 20 cases in the first clause and 15 cases for 20 cases in the second. It had been shown that while mortality was decreasing in hospitals in midwifery cases it was not decreasing outside. That bore out his argument for differentiating the cases as he had done in his amendment.

Dr. WALKER declared that he was in entire sympathy with Sir Charles Ball's amendment. As a teacher he did not believe that it was necessary for each student to have 20 cases. If he had resided in a maternity hospital for one month he would know a great deal more about midwifery at the end of the time than if he had conducted 100 cases on his own responsibility.

Sir CHARLES BALL'S amendment was lost on a show of hands.

The original motion as amended by the introduction of Dr. Langley Browne's proposal was then put as a substantive motion and agreed to.

Sir JOHN WILLIAMS then moved the adoption of the following recommendation of the committee:—

> No certificate that the student has conducted the above-mentioned 20 cases of labour should be accepted unless it is given by a member of the staff of a lying-in hospital, or of the maternity charity of a general hospital, or of a dispensary having an obstetric staff recognised for that purpose by the licensing bodies, or of a Poor-law infirmary having a resident medical officer as recognised.

Dr. LATIMER seconded the motion which was agreed to.

Sir JOHN WILLIAMS then moved:—

> That the attention of the licensing bodies should be called to the necessity in the public interest of instituting clinical and practical examinations in midwifery and gynæcology in connexion with each of the qualifying examinations.

Dr. LATIMER seconded the motion which was carried by 16 votes to 11. Four members who were present declined to vote.

It was also agreed that copies of the resolutions which had just been passed and of the reports of the Students Practical Midwifery Committee should be sent to the licensing bodies and teaching institutions of the United Kingdom.

The Report of the Education Committee.

On the motion of Dr. MACKAY the interim report of the Education Committee was received and entered in the minutes.

Dr. MACKAY then moved that the recommendation contained in the interim report of the committee should be adopted. Its terms ran thus:—

> That the President be authorised to apply to the licensing bodies for information regarding the dates at which the various professional examinations were entered for and completed in the cases of those of their licentiates the statistics of whose educational career are included in the table upon which the report is founded.

He proceeded to explain to the Council the scope of the requirements of the Council in regard to professional education." He wished it to be understood that the committee offered no opinion as to the manner in which the subjects should be combined or distributed for the purpose of teaching and examination.

Dr. NORMAN MOORE seconded the motion, which was carried.

Dr. MCVAIL then moved :—

> That the Medical Council is of opinion that when the subjects which are usually taken together are entered upon singly the pass standard should be at least 60 per cent.

The PRESIDENT said that before Dr. McVail spoke to his motion he would like to point out that the Council was asked by the Privy Council whether this ordinance was contrary to its existing regulations. However, they were now being invited by Dr. McVail to pass an *ad hoc* resolution which was not now on their books. He could not help thinking that was a dangerous course for the prestige of the General Medical Council. The motion was contrary to their actually existing resolution and therefore if it were carried it would mean rescinding the latter.

Dr. MCVAIL said that he must ask the kindness of the Council to allow him to explain the position. The Council, he might point out, was required to inspect the licensing bodies. What kind of inspection could they carry out if they were to have a man coming up for a single subject? They were asked by the University of Edinburgh to believe that the great bulk of the students would take their subjects in divisions. Who were the men who would take them in divisions? Would it be the good men or the weak men? He asked the Council to answer for themselves the question whether this proposed legislation was for strong men or weak men. It already happened that the University of Edinburgh had power under a particular ordinance.

The PRESIDENT : Excuse me interrupting you, Dr. McVail, but I might suggest that it would be better to keep out of these university matters and stick to the subject of the motion.

Dr. MCVAIL : Very well. He held that as the Privy Council had submitted the ordinance for the opinion of the General Medical Council they should make their representations in reply. He held that they were invited to make any observations which they had on it. Further, he might point out that this ordinance had a most important effect. It would at once lead to changes in many of the other licensing bodies. Of course, if the changes would be for the better, good and well. For his part he thought that they were very much for the worse. The ordinance would hinder the inspection work of the Council. The examiner would not see the student at work on more than one or two subjects. He did think that there was the gravest objection to the ordinance from the examination point of view and from the point of view of the inspection of examinations. It was very bad for the student, and the ordinance should not pass without the opinion expressed in his motion being placed before the Privy Council.

Sir JOHN MOORE seconded the motion. He understood that it was the intention of the Edinburgh faculty that the standard to be attained by students in the various subjects should be raised. However, he thought that the Council should express the opinion contained in Dr. McVail's motion. It was a most mischievous thing that students in the first years of their study should be allowed to take the subjects of examination piecemeal.

Dr. MACKAY thought that what Sir John Moore had mentioned with regard to the raising of the standard should bring the discussion to an end. They were all of opinion that a higher standard ought to be exacted when subjects were taken separately, but the University of Edinburgh had assured them that the standard there was to be heightened.

Sir THOMAS FRASER said that Dr. McVail had told them that the great object of the ordinance was merely to allow men to scrape through. That was nonsense.

Dr. MCVAIL : I did *not* say that. I said that the object of the ordinance was that men would be allowed to go in for examination in separate subjects.

Sir THOMAS FRASER : And the result would be that men would scrape through. That was not the case. The Edinburgh authorities, on the contrary, wanted to make their medical education more thorough and they could only do that by the changes which they proposed in the ordinance. He repudiated in the strongest and most emphatic manner the suggestion that the aim and object of this change of ordinance was to let men get through easily.

Dr. MCVAIL : I must take exception to that. Sir Thomas Fraser has imputed to me opinions which are not in my mind. I am speaking here as a member of the Examination Committee which has to satisfy the Privy Council in dealing with certain changes in the ordinance. The object of the ordinance is to let men through in single subjects.

The PRESIDENT : You have made your explanation, Dr. McVail. You are not entitled to make a second speech at this stage.

Sir THOMAS FRASER : I accept the explanation.

Dr. MCVAIL : It is not an explanation.

Sir THOMAS FRASER said that the passing of the motion of Dr. McVail might be a very serious matter. It had taken the Edinburgh authorities more than five years to determine upon the change. If the Privy Council accepted the suggestion the only course for them would be to throw out the ordinance. That would be a matter for deep regret.

The PRESIDENT pointed out that Dr. McVail's motion was not the motion of the Examination Committee. He (the President) was a member of the University Court of Glasgow which had taken a definite position against this ordinance. For himself he had determined when he was occupying the chair at the meetings of the General Medical Council that he must be absolutely neutral, and that he must guide it so that it might come on this occasion to a decision which was universal in its application and not particular to this ordinance. His view was that what the Council was now asked to do was to carry a motion which appeared to be generally uniform but which was only applicable to this particular case.

Dr. MCVAIL, in replying to the discussion, said that it was somewhat unfortunate in this connexion that he happened to be on the governing body of a university which opposed the principle of this ordinance. That university opposed it on the broad ground of general medical teaching. Personally he would therefore rather not have had to deal with this matter, but it had fallen to him officially to consider it as chairman of a committee. However, he could not advocate opinions which he did not believe. He could assure the Council that there was no desire on his part or on that of anyone with whom he had been connected to reflect in any way upon the University of Edinburgh. That University thought that by splitting up the subjects it would attain to a higher standard. He believed that it would not do so. The standard would be lowered and the influence on other institutions would be bad, and the ordinance would make the work of inspection on the part of the General Medical Council extremely difficult and of far less value than it had hitherto been.

On a division Dr. McVail's motion was defeated. Seven members voted in favour of it and 17 against it, whilst five members who were present declined to vote.

Mr. THOMSON then moved :—

> That the Council having considered the proposed ordinance of the University of Edinburgh find nothing therein which is contrary to the Council's resolution on professional education and examination.

Dr. MACKAY seconded the motion which was carried by 15 votes to three. Nine members present did not record votes.

Appointment of Registrar.

The Council unanimously agreed to reappoint Mr. H. E. Allen to the office of General Registrar.

Concluding Proceedings.

Replying to a vote of thanks,

The PRESIDENT said that he had been accused this session of having made the Council sweat. He was sure that he had drawn an equal amount of perspiration from himself. He thanked members for the sympathy which they had extended to him in the difficult position which he had that day occupied. From one point of view he sympathised with Dr. McVail, but he could not follow his own bent in that matter if by doing so he felt that he was leading the Council beyond the proper lines of action.

This concluded all the business on the agenda paper, and the session being at end the Council rose to meet again in November.

THE HANDEL COSSHAM MEMORIAL HOSPITAL.—The Handel Cossham Memorial Hospital, Kingswood, near Bristol, was formally opened on June 1st by the Right Hon. Augustine Birrell, M.P., in the presence of a very large gathering. It has been erected in accordance with the will of the late Mr. Handel Cossham, formerly M.P. for a division of Bristol. The cost of the building has been £30,000 and about £80,000 have been set aside for its maintenance and support.

He pointed out that this motion was brought forward to meet a state of affairs which had arisen in Mauritius. He said that instead of prohibiting the use of a title the colonies were with complete uniformity adopting an absolute prohibition of unqualified practice—a state of things which they hoped for in this country but which seemed to be far distant. The committee noted that under a Mauritius ordinance it was made unlawful under penalty for unqualified and unregistered dentists to practise in that colony. However, by a section of that ordinance the holders of British qualifications were placed in the same position as the holders of certain foreign diplomas as regarded practice in Mauritius. These foreign diplomas could be obtained under less stringent conditions than in this country, and would, on account of their insufficiency, not be recognised for registration in Great Britain. It was, however, the case that in certain other colonial ordinances a safeguard had been provided by the requirement that the diplomas of foreign countries should be recognised only in the case of those countries which provided reciprocal recognition for British registrable diplomas. The committee thought that all these circumstances should be brought under the notice of the Secretary of State for the Colonies.

Dr. LINDSAY STEVEN seconded the motion, which was agreed to without further discussion.

Examinations for the Services.

Dr. MCVAIL, as chairman of the Examination Committee, presented a report analysing the successes and failures of medical licentiates who had undergone the examinations for the Royal Navy Medical Service, the Royal Army Medical Corps, and the Indian Medical Service within the past eight months.

The report was received and entered on the minutes.

Students' Registration Committee.

Sir HUGH BEEVOR presented the report of the Students' Registration Committee, to which the Council gave its approval.

Appointment to Committees.

The following committees of the Council were then appointed:—

Examination Committee.—Dr. Pye-Smith, Mr. Young, and Dr. Caton (nominated by the English Branch Council); Sir Thomas Fraser, Dr. Finlay, and Dr. McVail (nominated by the Scottish Branch Council); and Sir Thomas Myles, Dr. Little, and Sir Charles Ball (nominated by the Irish Branch Council).

Education Committee.—Dr. Norman Moore, Sir G. Philipson, and Sir J. Williams (nominated by the English Branch Council); Dr. Mackay, Sir John Tuke, and Sir T. McCall Anderson (nominated by the Scottish Branch Council); and Dr. Little, Sir C. Nixon, and Sir John Moore (nominated by the Irish Branch Council).

Public Health Committee.—Dr. Cocking, Mr. Power, and Dr. Langley Browne (nominated by the English Branch Council); Dr. Norman Walker, Dr. Lindsay Steven, and Dr. McVail (nominated by the Scottish Branch Council), and Sir John Moore, Sir T. Myles, and Dr. Adye-Curran (nominated by the Irish Branch Council).

Pharmacopœia Committee.—The President (chairman), Dr. Norman Moore, Sir G. Philipson, Dr. Caton, Dr. Barrs, Sir Thomas Fraser, Dr. McVail, Sir John Moore, and Dr. Little.

Finance Committee.—Dr. Pye-Smith (chairman), Mr. Tomes, Sir John Tuke, and Dr. Little.

Dental Committee.—The President (chairman), Mr. Tomes, Mr. Hodsdon, and Sir Thomas Myles.

Dental Education and Examination Committee.—Mr. Tomes (chairman), Mr. Morris, Dr. Lindsay Steven, Dr. Finlay, Sir Thomas Myles, and Sir Charles Ball.

Students' Registration Committee.—Sir Hugh Beevor (chairman), Dr. Norman Moore, Sir John Tuke, Dr. Mackay, Sir C. Nixon, and Dr. Adye-Curran.

Executive Committee.—Sir Hugh Beevor, Dr. Pye-Smith, Mr. Young, Mr. Tomes, Sir John Tuke, Dr. McVail, Sir John Moore, and Sir Charles Ball.

Penal Cases Committee.—Dr. Saundby, Mr. Tomes, Dr. Finlay, and Sir C. Nixon.

The Council then adjourned until the following day.

FRIDAY, MAY 31ST.

The Council resumed its sittings at noon to-day, Dr. MACALISTER, the President, again occupying the chair.

The Report of the Pharmacopœia Committee.

Dr. NORMAN MOORE presented the report of the Pharmacopœia Committee and moved its adoption. The report contained a copy of the international agreement respecting the unification of the Pharmacopœial formulas for potent drugs signed at Brussels on Nov. 29th, 1906. The committee in the course of its report expressed the opinion that the time had now arrived when a communication should be addressed to the Royal Colleges of Physicians of London, of Edinburgh, and of Ireland, and to the other medical authorities, inviting their suggestions for the revision of the Pharmacopœia, in preparation for the next issue. A circular letter had accordingly been drafted and would shortly be issued by the President on behalf of the Council.

Sir JOHN MOORE seconded the adoption of the report which was agreed to without debate.

The Proposed Ordinance of the University of Edinburgh.

The Council then proceeded to consider reports submitted to it bearing on the alterations in regulations for degrees in medicine introduced into the proposed new ordinance of the University of Edinburgh. The Council had before it the sections of the ordinance at present in force and the provisions by which it was intended to supersede them. The proposed new ordinance contains the following provisions:—

> Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz.: first, in botany, zoology, physics, and chemistry; second, in anatomy and physiology; third, in pathology and materia medica and therapeutics; and fourth, in surgery and clinical surgery medicine and clinical medicine, midwifery, forensic medicine, and public health.
>
> Candidates who profess themselves ready to submit to an examination in any of the subjects comprised in the first division, viz.: botany, zoology, physics, and chemistry, may be admitted to examination in one, or in any number of, these subjects, at any examination held after they have attended the necessary qualifying course or courses in each of the subjects professed.
>
> Candidates who have passed their examinations in the subjects comprised in the first division may be admitted to examination in each of the subjects of the second division, after they have attended the necessary qualifying course or courses in that subject—viz., in physiology at any time; in anatomy at any time after the end of the first halfsession of their third winter session.
>
> Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in each of the subjects of the third division after they have attended the necessary qualifying course or courses in that subject—viz., in pathology at any time after the end of the third summer session in the case of those students who begin the medical curriculum in October, and at the end of the fourth summer session in the case of those students who begin their medical curriculum in May; and in materia medica at any time after the end of the fourth winter session: provided always that candidates may be admitted to examination in practical pharmacy, and also the physical, chemical, and botanical characters of medicinal substances, at any examination held after they have attended the necessary qualifying course of instruction in that subject.
>
> Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in each of the subjects of the fourth or final division after they have attended the necessary qualifying course or courses in that subject—viz., in forensic medicine and public health at any time; in midwifery at any time after the end of the first half-session of the fifth winter session; in practice of medicine and surgery at any time after the end of the fifth winter session; and in clinical medicine (including the subject of the diseases peculiar to women) and clinical surgery at the end of the fifth year of study.

The Examination Committee, after considering these sections, came to a resolution that they were not in accordance with the terms of the thirteenth recommendation on professional examination adopted by the General Medical Council on June 9th, 1896, which recommendation "suggests that a percentage of not less than 60—supposing that the pass requirement be 50 per cent.—should exempt from re-examination in such subject."

The PRESIDENT said that before they considered this matter he would like to express his wish that the resolution of the Examination Committee should not be entered upon the minutes in the form in which it stood, as the reference in it was misleading and historically inaccurate. He thought it was for the members of the Examination Committee to withdraw what was a mistaken reference.

The reports bearing on the subject of the proposed new Edinburgh ordinance, with the exception of the resolution referred to by the President, were then entered in the minutes.

Dr. MACKAY thereupon moved that the Council should adopt the report of the Education Committee to the effect that "the changes embodied in the proposed new ordinance of the University of Edinburgh are in accordance with the

Board. Public scavenging in part of the district is carried out by direct labour and in the rest by contractors, and the report compares the two systems to the advantage of the former. There is special need for the provision of a dust destructor and for the abolition of existing "tips" for refuse. The elementary schools of the district present many grave sanitary defects. The isolation hospital accommodation is limited and no attempt is made to isolate cases of scarlet fever. In dealing with the latter it is the custom of the sanitary authority to give free supplies of preparations of eucalyptus oil for inunction. The report contains an account of the local incidence of the principal infectious diseases in Ebbw Vale during the last five years. The infantile mortality-rate, in view of the general character of the district, cannot be considered exceptional: in the five years reviewed it has ranged between 125 and 169 per 1000 births. Dr. Farrar strongly urges the advantage of combining a series of districts in the neighbourhood, which are conveniently linked by railway communication, for the purpose of securing a medical officer of health who would be able to give the whole of his time to the supervision of the sanitary condition and administration of the areas under his charge.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Port of London.—The Aliens Act, 1905, which came into operation at the commencement of 1906 has apparently worked smoothly in the Port of London during its first year of operation. By the provisions of this Act any ship conveying more than 20 alien steerage passengers is an "immigrant" ship. This, at least, is the number fixed by the Secretary of State at the present juncture. During 1906 the total number of passengers arriving in the Port of London who were liable to examination under the Aliens Act was 14,939 and out of these a certain number were found to be "undesirable" on medical grounds and were refused leave to land. With reference to plague, it appears that the French Government now insists upon the destruction of rats by means of a special apparatus in the case of ships coming from a port regarded as being "infected" with plague or having called at such a port, and in the case of ships having taken on board more than 50 tons of merchandise coming directly from a country considered to be "infected" with plague. These regulations apply even to ships which have already discharged the whole of their cargo in one or more foreign ports. In Great Britain destruction of rats is only required when plague has occurred either in persons or in rats on board ship. With reference to cockle-borne enteric fever it is gratifying to find that the corporation has apparently succeeded in preventing the laying down of cockles taken from the Maplin sands in the sewage-polluted water of Leigh Creek, where they are placed to "cleanse" themselves from the gritty sand which collects in their branchiæ and other parts while on the sands. Some interesting analyses of Thames water from Teddington to the Nore have recently been made by the City analyst, but, as a matter of fact, they do not add much to the knowledge which we already possess as the results of chemical analyses made by Royal Commissions in former years and of the work done in a bacteriological sense by Dr. A. C. Houston for the present Royal Commission on Sewage Disposal and for the London County Council. The samples dealt with by Dr. Herbert Williams in his current annual report were all taken, in order to insure uniformity in comparison, during the last one and a half hours of ebb tide—i.e., during the period of greatest concentration. The samples show, what must obviously be the case, that the water coming over Teddington Weir is already polluted. The fact that it receives between Oxford and Teddington either directly or indirectly the sewage effluents of the valley of the Thames is sufficient to account for this fact and the remarkable circumstance connected with the occurrence is that the population of London drinks the water from this source, after filtration, with, in so far as water-borne diseases are concerned, almost, if not quite, absolute impunity. Between Teddington Weir and London Bridge the analyses show some increase in pollution, a fact which may be perhaps explained by the circumstance that the sewage of effluents of Richmond, Kew, and Sheen, as well as storm outfalls from the main intercepting sewers of the London County Council, discharge into this portion of the river. It is well to remember in connexion with these storm outfalls that in certain circumstances the liquid discharged therefrom may be almost crude sewage. At Greenhithe the river has received for the last five miles of its course the effluent from the Barking and Crossness outfalls—i.e., some 250,000,000 gallons daily—but ere Gravesend is reached the degree of pollution is only about the same as that found at Greenwich. It is stated that the effluent from the Leigh sewage outfall near Southend is much more impure than that from Barking, where, be it noted, precipitation and subsidence have alone been resorted to. Some details as to the installation at Leigh would have been instructive, as we seem to have read somewhere that a very considerable sum was spent upon a biological process. But one of the worst offenders of all the towns along the Thames estuary would appear to be Southend, where, according to the report before us, "crude sewage containing masses of human excrement was pouring out in great volume and the odour given off was extremely offensive." Moreover, "the stream of sewage could be distinctly traced for nearly a mile by the scum visible upon the surface of the water as well as by floating human excrement." The general conclusion at which Dr. Williams arrives is that, although there is a considerable amount of sewage entering the river Thames and river Medway, the general condition of the water within the district of the Port of London sanitary authority "cannot be considered as being in a state of serious pollution." It may be added, too, that Southend intends to purify its sewage at a cost of about £150,000. In the matter of the importation of food Dr. Williams states with reference to the large quantities of boned meat and casks of sausage meat that none of it could be determined to be unsound and consequently it had to be passed for human consumption, but he adds that in the case of meat which is cut up into small pieces there is no means of determining that it has not come from animals the subject of disease in some form or other, nor is there any sufficient guarantee that such meat has been derived from only those animals which in this country we are accustomed to devote to human food. Certain consignments of "blown" tins were condemned. Suggestions were made by Dr. Williams during the year for the amendment of the Merchant Shipping Act, 1906, such suggestions being mainly directed to the necessity for the plans of all ships built in any port being submitted to the medical officer of health of such port for approval as regards the adequacy of cubic space, &c. While we entirely concur in the desirability for improvement in this respect it appears to us that to submit the plans of vessels built in small ports to the local medical officer of health would lead to a great diversity in the requirements and that some definite and improved standards had better in the first place be laid down for general guidance.

Borough of East Ham.—Dr. G. Sowden does not regard the provision of a municipal milk depôt as the panacea for a high infantile mortality. Such institutions are useful, but for his part he would prefer to spend the money available upon the employment of a lady health visitor. As a result of investigation into infantile diarrhœa in East Ham during the months of August and September last it was found that 78 per cent. of such mortality occurred in children fed either wholly or partially on cow's or condensed milk, while out of 98 deaths from diarrhœa only five children were entirely breast-fed. Dr. Sowden thinks that it is insanitary house conditions which are very largely responsible for deaths from infantile diarrhœa. He points out that condensed milk as purchased is nearly sterile and that, if so, seeing that 40 per cent. of the deaths from diarrhœa are in children fed on condensed milk the pollution must have taken place in the home. He adds that as a tin of condensed milk usually lasts several days, and that during this time it is not infrequently left uncovered and exposed to dust and flies, its contamination is not a matter for surprise. What is necessary is the diminished use of condensed and cow's milk and more breast-feeding, together with greater cleanliness in the children and their surroundings. The remedy for infantile diarrhœa is, Dr. Sowden urges, the encouragement of breast-feeding and not, as is done by municipal milk depôts, the encouragement of artificial feeding. It should, however, be added that many of the existing milk depôts quite accept this position and only assent to the use of sterilised milk as a *pis aller* when the mothers cannot for one or another reason suckle their offspring. Elsewhere in his report Dr. Sowden furnishes some interesting data relative to the use of condensed milk. Such milk is divided into condensed whole milk—i.e., milk containing the whole of its cream—and condensed skim milk from which practically the whole of the fat has been removed. This latter is popularly known as "Starvation Brand." Investigations in East Ham showed that in eight

NOTES UPON HEALTH RESORTS.

THE BRINE BATHS OF DROITWICH.

DROITWICH was the scene of an interesting ceremony on Saturday, June 1st, on the occasion of the opening of extensions to the world-famous brine baths. It speaks well for the reputation of this quaint, restful place as a health resort that the number of visitors undergoing treatment there steadily increases year by year, and the little borough has moved with the times and, determined not to be outstripped by continental spas, has made a praiseworthy attempt to provide for its visitors improved accommodation and to increase such comforts as minister to the needs of those particular cases which are benefited by saline bath treatment. The class of patient to which Droitwich appeals most includes sufferers from muscular rheumatism, sciatica, and chronic gout, and there can be no doubt that these and others gain relief by a course of warm natural brine baths. The waters of Droitwich enjoy the distinction of being the strongest natural brine found in Europe. The total salts amount to no less than 50 ounces per gallon, which is ten times as much as is contained in a gallon of sea-water. Common salt, however, is not the only constituent, for there are present also sodium sulphate, magnesium chloride, sodium iodide, and calcium sulphate. Droitwich brine is richer in salines than even the waters of the Dead Sea. Suitably diluted the water acts as a purgative saline when taken internally. Further, Droitwich brine is decidedly radio-active, or at least yields a gas on boiling which exhibits marked radio-active effects. It seems probable that radio-activity is an important factor in balneo-therapeutics and may possibly account for the therapeutic effects of natural water being so marked, while frequently waters artificially prepared are not analogous in their action.

At the opening ceremony referred to an interesting account of the history of Droitwich was given by the town clerk. It appears that Droitwich, under the name Salinæ, was a town of considerable importance in the time of the Romans, but the first record of the manufacture of salt is in A.D. 816, when Kenulph, King of Mercia, endowed the great church at Worcester with ten salt furnaces at Droitwich. At this time the town was called Wyche, from the Scandinavian "wic," a shallow bay for the evaporation of sea-water, and hence any place where salt is manufactured. The prefix "droit" was given by Edward III., the word signifying the granting of a royal assent or right to manufacture salt in the town. The therapeutic effects of an immersion in Droitwich brine were apparently first observed during the cholera visitation of 1832, certain sufferers having been put into the heated brine because no other hot water happened to be available. In 1836 the Royal Brine Baths were opened and since that time a very large number of patients suffering from rheumatism, sciatica, gout, and nervous disorders have sought relief at Droitwich. The baths have now grown to the dimensions of a continental spa, hotel accommodation has been increased and improved, and every effort is being put forward to make the place attractive to the visitors. The extensions to the brine baths, known as St. Andrew's Brine Baths, which were formally opened by the Earl of Coventry, Lord Lieutenant of the county of Worcester, were decided upon by the late Mr. Thomas Cobbett, but on his death over a year ago the work was taken in hand by the present trustees of the estate, Lord Cobham and Mr. J. W. Willis Bund. The additions consist of an enlarged entrance hall, lounge, waiting rooms, and a new series of ladies' baths, all well planned, substantially built, and conducive to the comfort of the patient. In addition there are two large swimming baths, one for ladies and one for gentlemen. "Swimming baths" is, however, hardly the correct term to apply, since so buoyant is the water that it is impossible to swim in it, and any effort to swim terminates in a few futile kicks of the legs in the air. In the erect position the patient sinks to about the level of his armpits. In treatment by immersion the patient's body is kept under the brine by means of bars of wood placed across the bath. The temperature is regulated by means of steam which is turned directly into the brine.

Amongst those present at the opening ceremony on Saturday were several medical men from London and the provinces who were entertained at luncheon in the Salters' Hall by the mayor (Councillor C. J. Pond) and corporation. Appropriate speeches were made by the Mayor, Lord Cobham, Mr. Harmsworth, M.P., and Dr. F. de Havilland Hall. The last-named gentleman proposed the toast of "Success to Droitwich," and he expressed the hope that the day's proceedings would be the means of impressing upon the medical profession that there were no brine baths of the same kind anywhere in Europe or indeed anywhere else in the world. The toast "The Medical Profession" was proposed by Mr. Harmsworth and was replied to by Dr. G. W. Hamilton Cumming and Mr. E. Shirley Jones. A conversazione held in the Salters' Hall in the evening brought a very pleasant and successful day's proceedings to a close.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances and Administration of the Ebbw Vale Urban District, with special reference to the Prevalence of Infectious Diseases therein, by Dr. R. A. FARRAR.[1]—Dr. Farrar gives some interesting particulars regarding housing questions in Ebbw Vale, a Monmouth district with a population of about 25,000, occupied mainly in mining, smelting, forging, and similar works. Not long ago this district was conspicuous for the squalor and insanitary condition of most of its house property, and many dwellings and their surroundings are still in a very objectionable state. But recently well-planned and well-built artisans' houses have been erected at the rate of between 100 and 200 in each year and at present there are no signs of diminution in building activity. The competition for new houses is keen and they are taken up as fast as they can be built. The principal credit for the great alteration thus effected is due to the establishment of building clubs among persons employed by the Ebbw Vale Steel, Iron, and Coal Company. The company, which employs about 7000 workmen, has financed the building clubs by advancing the necessary money for building (at 4 per cent.), and has also in most instances leased the sites at a very moderate ground rent and given stone free for the labour of quarrying it. The company holds the title deeds of houses built by the clubs until such time as they become by purchase the absolute property of the members renting them. The usual arrangement is to pay 3*s*. a week to the sinking fund in addition to the rent of the house, which is usually about 6*s*. a week. Various provisions are made to meet delays in payment and to enable members to tide over periods of sickness. The clubs are limited to a membership of 20 and about 17 have so far been formed. An appendix to the report gives in full the rules which are adopted. Dr. Farrar reports favourably on the character and sanitary condition of these building-club dwellings. Houses rented at 6*s*. a week contain, on the ground floor, a sitting-room, front and back kitchens, a bath-room with hot and cold water laid on, and a pantry, and upstairs there are three bedrooms. Most of them have garden plots and the report recommends that cultivation of these plots should be insisted upon as a condition of tenancy. In addition to the above building clubs various building societies are doing a considerable business in the district. One of these societies makes a speciality of houses built of cement-concrete blocks ten inches thick with a hollow space within of three and a half inches. Houses built of these blocks are warmer and drier than those built of solid brick or stone, and the material, made from waste slag, is found to be cheaper than brick. There are evidently many conditions in Ebbw Vale to which serious objection must be taken by the sanitarian, but it is satisfactory to note that in some of these matters the district is passing through the same kind of transition stage as can be seen in the case of its housing. The public water-supply is being supplemented by the construction of a new reservoir of 180 million gallons capacity and the district will soon participate in the extensive works of sewerage now being carried out by the Western Valleys Sewerage

Board. Public scavenging in part of the district is carried out by direct labour and in the rest by contractors, and the report compares the two systems to the advantage of the former. There is special need for the provision of a dust destructor and for the abolition of existing "tips" for refuse. The elementary schools of the district present many grave sanitary defects. The isolation hospital accommodation is limited and no attempt is made to isolate cases of scarlet fever. In dealing with the latter it is the custom of the sanitary authority to give free supplies of preparations of eucalyptus oil for inunction. The report contains an account of the local incidence of the principal infectious diseases in Ebbw Vale during the last five years. The infantile mortality-rate, in view of the general character of the district, cannot be considered exceptional: in the five years reviewed it has ranged between 125 and 169 per 1000 births. Dr. Farrar strongly urges the advantage of combining a series of districts in the neighbourhood, which are conveniently linked by railway communication, for the purpose of securing a medical officer of health who would be able to give the whole of his time to the supervision of the sanitary condition and administration of the areas under his charge.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Port of London.—The Aliens Act, 1905, which came into operation at the commencement of 1906 has apparently worked smoothly in the Port of London during its first year of operation. By the provisions of this Act any ship conveying more than 20 alien steerage passengers is an "immigrant" ship. This, at least, is the number fixed by the Secretary of State at the present juncture. During 1906 the total number of passengers arriving in the Port of London who were liable to examination under the Aliens Act was 14,923 and out of these a certain number were found to be "undesirable" on medical grounds and were refused leave to land. With reference to plague, it appears that the French Government now insists upon the destruction of rats by means of a special apparatus in the case of ships coming from a port regarded as being "infected" with plague or having called at such a port, and in the case of ships having taken on board more than 50 tons of merchandise coming directly from a country considered to be "infected" with plague. These regulations apply even to ships which have already discharged the whole of their cargo in one or more foreign ports. In Great Britain destruction of rats is only required when plague has occurred either in persons or in rats on board ship. With reference to cockle-borne enteric fever it is gratifying to find that the corporation has apparently succeeded in preventing the laying down of cockles taken from the Maplin sands in the sewage-polluted water of Leigh Creek, where they are placed to "cleanse" themselves from the gritty sand which collects in their branchiæ and other parts while on the sands. Some interesting analyses of Thames water from Teddington to the Nore have recently been made by the City analyst, but, as a matter of fact, they do not add much to the knowledge which we already possess as the results of chemical analyses made by Royal Commissions in former years and of the work done in a bacteriological sense by Dr. A. C. Houston for the present Royal Commission on Sewage Disposal and for the London County Council. The samples dealt with by Dr. Herbert Williams in his current annual report were all taken, in order to insure uniformity in comparison, during the last one and a half hours of ebb tide—i.e., during the period of greatest concentration. The samples show, what must obviously be the case, that the water coming over Teddington Weir is already polluted. The fact that it receives between Oxford and Teddington either directly or indirectly the sewage effluents of the valley of the Thames is sufficient to account for this fact and the remarkable circumstance connected with the occurrence is that the population of London drinks the water from this source, after filtration, with, in so far as water-borne diseases are concerned, almost, if not quite, absolute impunity. Between Teddington Weir and London Bridge the analyses show some increase in pollution, a fact which may be perhaps explained by the circumstance that the sewage of effluents of Richmond, Kew, and Sheen, as well as storm outfalls from the main intercepting sewers of the London County Council, discharge into this portion of the river. It is well to remember in connexion with these storm outfalls that in certain circumstances the liquid discharged therefrom may be almost crude sewage. At Greenhithe the river has received for the last five miles of its course the effluent from the Barking and Crossness outfalls—i.e., some 250,000,000 gallons daily—but ere Gravesend is reached the degree of pollution is only about the same as that found at Greenwich. It is stated that the effluent from the Leigh sewage outfall near Southend is much more impure than that from Barking, where, be it noted, precipitation and subsidence have alone been resorted to. Some details as to the installation at Leigh would have been instructive, as we seem to have read somewhere that a very considerable sum was spent upon a biological process. But one of the worst offenders of all the towns along the Thames estuary would appear to be Southend, where, according to the report before us, "crude sewage containing masses of human excrement was pouring out in great volume and the odour given off was extremely offensive." Moreover, "the stream of sewage could be distinctly traced for nearly a mile by the scum visible upon the surface of the water as well as by floating human excrement." The general conclusion at which Dr. Williams arrives is that, although there is a considerable amount of sewage entering the river Thames and river Medway, the general condition of the water within the district of the Port of London sanitary authority "cannot be considered as being in a state of serious pollution." It may be added, too, that Southend intends to purify its sewage at a cost of about £150,000. In the matter of the importation of food Dr. Williams states with reference to the large quantities of boned meat and casks of sausage meat that none of it could be determined to be unsound and consequently it had to be passed for human consumption, but he adds that in the case of meat which is cut up into small pieces there is no means of determining that it has not come from animals the subject of disease in some form or other, nor is there any sufficient guarantee that such meat has been derived from only those animals which in this country we are accustomed to devote to human food. Certain consignments of "blown" tins were condemned. Suggestions were made by Dr. Williams during the year for the amendment of the Merchant Shipping Act, 1906, such suggestions being mainly directed to the necessity for the plans of all ships built in any port being submitted to the medical officer of health of such port for approval as regards the adequacy of cubic space, &c. While we entirely concur in the desirability for improvement in this respect it appears to us that to submit the plans of vessels built in small ports to the local medical officer of health would lead to a great diversity in the requirements and that some definite and improved standards had better in the first place be laid down for general guidance.

Borough of East Ham.—Dr. G. Sowden does not regard the provision of a municipal milk depôt as the panacea for a high infantile mortality. Such institutions are useful, but for his part he would prefer to spend the money available upon the employment of a lady health visitor. As a result of investigation into infantile diarrhœa in East Ham during the months of August and September last it was found that 78 per cent. of such mortality occurred in children fed either wholly or partially on cow's or condensed milk, while out of 98 deaths from diarrhœa only five children were entirely breast-fed. Dr. Sowden thinks that it is insanitary house conditions which are very largely responsible for deaths from infantile diarrhœa. He points out that condensed milk as purchased is nearly sterile and that, if so, seeing that 40 per cent. of the deaths from diarrhœa are in children fed on condensed milk the pollution must have taken place in the home. He adds that as a tin of condensed milk usually lasts several days, and that during this time it is not infrequently left uncovered and exposed to dust and flies, its contamination is not a matter for surprise. What is necessary is the diminished use of condensed and cow's milk and more breast-feeding, together with greater cleanliness in the children and their surroundings. The remedy for infantile diarrhœa is, Dr. Sowden urges, the encouragement of breast-feeding and not, as is done by municipal milk depôts, the encouragement of artificial feeding. It should, however, be added that many of the existing milk depôts quite accept this position and only assent to the use of sterilised milk as a *pis aller* when the mothers cannot for one or another reason suckle their offspring. Elsewhere in his report Dr. Sowden furnishes some interesting data relative to the use of condensed milk. Such milk is divided into condensed whole milk—i.e., milk containing the whole of its cream—and condensed skim milk from which practically the whole of the fat has been removed. This latter is popularly known as "Starvation Brand." Investigations in East Ham showed that in eight shops situated in the more populous parts very many dozen tins of condensed skim milk were sold weekly. We quite agree with Dr. Sowden as to the importance of educating the working-class mothers up to the standard of appreciating the real difference between these brands and also to the fact that the skim variety is often labelled in misleading fashion. No better means of education in this sense can be devised than the teaching of elementary hygiene to the older school girls and Dr. Sowden has, we are glad to see, written some notes on infant feeding for the use of teachers in the schools.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8940 births and 4442 deaths were registered during the week ending June 1st. The annual rate of mortality, which had steadily declined from 17·9 to 14·9 per 1000 in the eight preceding weeks, further fell to 14·5 in the week under notice. During the first nine weeks of the current quarter the death-rate in these towns averaged 16·0 per 1000, the rate in London during the same period being 15·5. The lowest annual death-rates in the 76 towns during the week were 3·5 in Hornsey, 5·8 in Rotherham, 7·1 in Handsworth (Staffs.), 7·6 in East Ham, and 7·8 in Croydon; in the other towns the rates ranged upwards to 20·2 in Oldham, 20·4 in Sunderland, 22·0 in St Helens, 25·7 in Bolton, and 35·3 in Middlesbrough. The 4442 deaths in the 76 towns showed a further decrease of 136 from the number in the preceding week, and included 474 which were referred to the principal infectious diseases, against 507 and 474 in the two previous weeks; of these, 201 resulted from measles, 111 from whooping-cough, 48 from diphtheria, 47 from diarrhœa, 45 from scarlet fever, and 22 from "fever" (principally enteric), but not any from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 1·5 per 1000, the rate from the same diseases in London being 1·4. No death from any of these epidemic diseases was registered last week in Southampton, Norwich, Wolverhampton, Swansea, York, Devonport, or in six other of the 76 towns; the annual death-rates therefrom, however, ranged upwards to 3·0 in Tottenham, 3·3 in Portsmouth, 3·9 in Hanley, 4·3 in Sunderland, 5·2 in Grimsby, 9·1 in Bolton, and 9·2 in Middlesbrough. The 201 fatal cases of measles showed a further slight decline from the high numbers in the two preceding weeks; the death-rates from this disease ranged upwards to 2·7 in Sunderland, 3·0 in Portsmouth, 3·1 in Hanley, and 7·7 in Bolton and in Middlesbrough. The deaths from whooping-cough, which had declined from 176 to 116 in the four preceding weeks, further fell to 111 during the week under notice, the highest death-rates from this cause being 1·1 in Huddersfield, 1·2 in West Ham, Walthamstow, and Wigan, 1·3 in Salford, and 2·2 in Grimsby. The fatal cases of diphtheria, which had been 41 and 46 in the two preceding weeks, further rose last week to 48 and included 14 in London and three each in Bristol, Birmingham, and Sunderland. The deaths from diarrhœa, which had been 51 in each of the two preceding weeks, declined to 47 in the week under notice, the greatest proportional mortality being recorded in Walsall and St. Helens. Scarlet fever caused a death-rate of 1·4 in King's Norton, and "fever" a rate of 1·5 in Grimsby. No fatal case of small-pox was registered in any of the 76 towns; and no cases of this disease were under treatment in the Metropolitan Asylums Hospitals during the week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2658, 2679, and 2732 at the end of the three preceding weeks, had further risen to 2824 at the end of the week under notice; 437 new cases were admitted during the week, against 349, 363, and 382 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had declined from 412 to 230 in the eight preceding weeks, further fell to 192 last week, and were 20 below the corrected average in the corresponding weeks of the previous five years. The causes of 37, or 0·8 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Newcastle-on-Tyne, and in 64 other of the 76 towns; the proportion of uncertified deaths, however, again showed a marked excess in Liverpool, Birmingham, Sunderland, and St. Helens.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·7 and 17·5 per 1000 in the two preceding weeks, further declined to 16·7 in the week ending June 1st, but exceeded the rate in the 76 English towns by 2·2. The rates in the eight Scotch towns ranged from 9·3 in Aberdeen and 12·0 in Dundee to 18·6 in Glasgow and 20·5 in Greenock. The 580 deaths in the eight towns showed a decrease of 27 from the number in the preceding week, and included 91 which were referred to the principal epidemic diseases, against 112 and 92 in the two preceding weeks. These 91 deaths were equal to an annual rate of 2·6 per 1000, which exceeded by 1·1 the rate from the same diseases in the 76 English towns; they included 38 which were referred to whooping-cough, 24 to "fever," 14 to diarrhœa, seven to measles, six to diphtheria, two to scarlet fever, and none to small-pox. The 38 fatal cases of whooping-cough showed a slight decline from the numbers in recent weeks, and included 26 in Glasgow, seven in Edinburgh, and two each in Paisley and in Greenock. The deaths referred to different forms of "fever," which had been 36, 41, and 28 in the three preceding weeks, further declined to 24, of which 20 occurred in Glasgow, two in Leith, and one each in Edinburgh and in Aberdeen; 17 deaths were certified as cerebro-spinal meningitis in Glasgow, two in Leith, and one in Edinburgh. The fatal cases of diarrhœa, which had been seven and nine in the two preceding weeks, further rose to 14 in the week under notice, and included seven in Glasgow, two in Edinburgh, and two in Dundee. Of the seven deaths from measles four were registered in Edinburgh and two in Glasgow, while of the six fatal cases of diphtheria three occurred in the latter and two in the former city. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had declined from 127 to 83 in the four preceding weeks, were 82 in the week under notice, and were 13 below the number in the corresponding week of last year. The causes of 23, or 4 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; the proportion of uncertified deaths in the 76 English towns during the same week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 26·7 and 25·8 per 1000 in the two preceding weeks, further declined to 23·1 in the week ending June 1st. During the first nine weeks of the current quarter the death-rate has averaged 26·8 per 1000; the mean rate during the same period did not exceed 15·5 in London and 17·7 in Edinburgh. The 173 deaths of Dublin residents registered during the week under notice showed a decline of 20 from the number in the preceding week, and included 13 which were referred to the principal epidemic diseases, against seven and 17 in the two preceding weeks; of these, eight resulted from whooping-cough, four from measles, and one from "fever," but not any from small-pox, scarlet fever, diphtheria, or diarrhœa. These 13 deaths were equal to an annual rate of 1·7 per 1000, the rate during the same week from the principal epidemic diseases being 1·4 in London and 2·6 in Edinburgh. The fatal cases of whooping-cough, which had been eight, four, and ten in the three preceding weeks, declined again last week to eight; while the fatal cases of measles numbered four in the week under notice, having been six, one, and six in the three preceding weeks. The 173 deaths from all causes included 25 of children under one year of age and 55 of persons aged upwards of 60 years; the deaths of infants showed a decline, while those of elderly persons considerably exceeded the number in the previous week. Five inquest cases and six deaths from violence were registered; and 76, or nearly 44 per cent., of the deaths occurred in public institutions. The causes of four, or 2·3 per cent., of the deaths in Dublin last week were not certified; only one death in London was uncertified, while in Edinburgh the proportion was 6·8 per cent. The 156 deaths registered in Belfast during the week under notice included 14 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: J. E. Robinson to the *New Zealand*, on recommissioning; W. Hackett to the *Goliath*, on recommissioning; A. G. W. Bowen to the *Canopus*, on recommissioning; and E. St. M. Nepean to the *Niobe*. Staff Surgeons: M. L. B. Rodd and A. J. Laurie to the *Mars*, on recommissioning. Surgeons: W. F. Archibald to the *Goliath*; T. A. Smyth to the *Canopus*, on recommissioning; J. C. F. D. Vaughan to the *Hebe*; A. C. Renwick to the *New Zealand*, on recommissioning; E. B. Kenny to the *Indus*; and J. O'Hea to R.M.A., Eastney.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Henry John Hadden has been placed on the Retired List, at his own request *(dated June 2nd, 1907)*.

ROYAL ARMY MEDICAL CORPS.

Captain W. H. S. Nickerson, V.C., lately serving in West Africa, has been appointed to the Dublin district for duty.

INDIAN MEDICAL SERVICE.

The services of Captain S. H. L. Abbott have been placed at the disposal of the Government of India for plague duty in the Punjab.

The King has approved of the transfer to the temporary half-pay list of the under-mentioned officers: Captain Stewart Ranken Douglas (dated Sept. 16th, 1905); and Captain Harold Budgett Meakin (dated March 23rd, 1907).

The King has also approved of the retirement from the service of the undermentioned officers: Lieutenant-Colonel Osborne Henry Channer (dated April 15th, 1907); Major Wilfred Ernest Arbuthnot Armstrong (dated March 12th, 1907); and Lieutenant John Henry Gill (dated March 27th, 1907).

VOLUNTEER CORPS.

Rifle: 6th Volunteer Battalion the Royal Scots (Lothian Regiment): Arthur Julian de Spiganovicz to be Surgeon-Lieutenant (dated March 1st, 1907). 2nd Volunteer Battalion the East Lancashire Regiment: Surgeon-Major W. Deans is granted the honorary rank of Surgeon-Lieutenant-Colonel and resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 1st, 1907). 1st Cadet Battalion the King's Royal Rifle Corps: Acting Surgeon J. H. Reynolds, V.C. (Lieutenant-Colonel, retired pay), resigns his appointment (dated April 22nd, 1907). 1st Dumbartonshire Volunteer Rifle Corps: Surgeon-Lieutenant F. Gracie to be Surgeon-Captain (dated April 22nd, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Cadet Corps (St. Michael's, Woolwich) attached to the Eastern Command: Woolwich Companies: The announcement of the resignation of his commission by Captain J. P. Ekins is cancelled.

ROYAL ARMY MEDICAL CORPS REGULATIONS.

New regulations for admission to the Royal Army Medical Corps have now been issued. Candidates who have been specially employed in consequence of a national emergency, either as an officer or in a position usually filled by an officer, will be allowed to reckon such service towards retired pay and gratuity, and if over the regulation limit of age at the date of commencement of the competitive examination shall be permitted to deduct from their actual age any period of that service if such reduction will bring them within the age limit.

THE KING'S LEVÉE: HEROES OF THE INDIAN MUTINY.

At the Levée held at St. James's Palace on June 3rd by the King a number of naval and military officers and civilians who served in the Indian Mutiny were in attendance in order that His Majesty might mark the fiftieth anniversary of that campaign by receiving survivors. Field-Marshal Lord Roberts in introducing the survivors of the siege of Delhi did so as the leader and senior of them. The Mutiny campaign, it may be mentioned, yielded the greatest number of Victoria Crosses of any war, the total gained being 182, as against 111 for the Crimea and 78 for the last South African war. The following medical officers who took part in the siege of Delhi and the defence and relief of Lucknow attended the Levée: Deputy Surgeon-General J Fairweather, Deputy Surgeon-General C. A. Innes, Surgeon-Major H. M. Greenhow, and Brigade-Surgeon H. E. Busteed, C.I.E.

THE ORDER OF ST. JOHN OF JERUSALEM.

The annual commemoration service of the Order of St. John of Jerusalem in England will be held at St. John's Church, Clerkenwell, on June 24th, at 2.15 P.M. The service will be followed by a general assembly of members and associates of the Order at St. John's Gate.

Correspondence.

"Audi alteram partem."

UNION OF MEDICAL SOCIETIES.

To the Editors of THE LANCET.

SIRS,—The following societies have decided to amalgamate, viz.:—

	Established.
Royal Medical and Chirurgical Society	1805
Pathological Society of London	1846
Epidemiological Society	1850
Odontological Society of Great Britain	1856
Obstetrical Society of London	1858
Clinical Society of London	1867
Dermatological Society of London	1882
British Gynæcological Society	1884
Neurological Society	1886
British Laryngological, Rhinological, and Otological Association	1888
Laryngological Society of London	1893
Dermatological Society of Great Britain and Ireland	1894
British Electrotherapeutic Society	1901
Therapeutical Society	1902

The Otological Society of Great Britain and Ireland (1899) will give its decision on June 10th. His Majesty the King has graciously granted the petition of the above societies that the amalgamation shall be known as the Royal Society of Medicine. The new Society will be housed at 20, Hanover-square. The balance of assets over liabilities is more than £37,000. The estimated balance of income over expenditure is about £1000. This estimate is based on subscriptions actually promised. As answers have yet to be received from 700 persons entitled to join the new society, and as many members of the profession who are not members of the amalgamating societies and therefore are not entitled to be proposed for election until the society has been constituted, have expressed their desire to join, the balance of income over expenditure will be increased. The first meeting of the Fellows of the Royal Society of Medicine will be held at 20, Hanover-square, on Friday, June 14th, at 5.30 P.M. for the purpose of adopting by-laws and electing the council and honorary officers.

We are, Sirs, yours faithfully,

ARTHUR LATHAM.
HERBERT S. PENDLEBURY.
Honorary Secretaries of the Committee of Representatives of the Societies.

June 4th, 1907.

To the Editors of THE LANCET.

SIRS,—The recent amalgamation of several of the medical societies under the title of the Royal Society of Medicine is an event with regard to which many members of the profession will rejoice. It also seems to me to be an occasion for the adoption of certain small reforms the desirability of one of which at least has been forcibly impressed upon me by the receipt of a circular of a society which will henceforth form one of the sections of the Royal Society of Medicine. In this circular a list is given of names proposed by the council of the society for election as officers and members of council of the section for the year 1907-08. In this list is noticeable what would appear to be an invidious distinction—that is to say, that amongst the names of 29 gentlemen one alone appears without any title at all. On further perusing the list two other well-known surgeons are also found to be destitute of medical titles, though in this case evidence is given of their having received honours—eminently well won—

from the King. The explanation of the whole matter is evidently that university titles, medical and surgical, are alone recognised. Surely this is not desirable. What have the Presidents of the various Colleges of Physicians and Surgeons to say on the matter? (If I remember rightly a similar course is pursued with regard to the official issue of the names of the successful candidates for admission into the Royal Navy and Army Medical Services.) It is possible that a member possessing the qualifications of F.R.C.S. Eng. and M.D. Brussels would be designated in these lists by the latter and not by the former title, which, without wishing in any way to disparage the examination for the M.D. Brussels, seems to be absurd. It is to be hoped that the Royal Society of Medicine will inaugurate a little more liberal and a little less invidious spirit. Let me add that I have no personal interest whatever in the matter, having, in fact, been educated at a university and not possessing a Fellowship of any of the Royal Colleges.

I am, Sirs, yours faithfully,
London, June 3rd, 1907. LIBRA.

THE NEW VACCINATION ORDER.

To the Editors of THE LANCET.

SIRS,—The Local Government Board has just issued a General Order about vaccination to "boards of guardians, public vaccinators, and all others whom it may concern," which, when working in conjunction with Mr. Burns's new Vaccination Bill, which passed the second reading in the House of Commons on Friday, May 24th, virtually means the repeal of the Vaccination Acts. Let us see what will be the effect of this new Order and this new Bill. Let us take the new Bill first, which when it becomes law will allow the so-called conscientious objector to simply make a statutory declaration before a commissioner for oaths, or justice, and pay 1*s.* or 1*s.* 6*d.*, and thus be exempt from the Act. But this is not all. For when a baby is three months old the vaccination officer, according to the new Order, must notify the parent of the date when the child will be four months old, and tell him that if he does not receive a legal exemption or a certificate within seven days from that date, the public vaccinator will be instructed to call and offer to vaccinate. This means that the vaccination officer is to write and warn the people that they have only another month in which to obtain their exemption, and so they had better bestir themselves. In other words, the vaccination officer is to stultify himself by warning the people not to do what he was placed there originally to enforce. Now the conscientious objector is really a very small minority, although perhaps somewhat a noisy one, but he does not give any real trouble, and in spite of him the people are to-day better vaccinated than ever they have been. There are, however, a great number of people, less earnest than the conscientious objector, "who do not believe in it," and who "think it a shame to cut the poor little mite about," and a very great number who think it "nonsense" and a "lot of trouble." These people take it as a matter of course and submit, but when shown how easy it is to become exempted they will willingly make the declaration and so save themselves trouble and thus become a danger to the rest of the public. A good many of the public believe that small-pox has been, and can be, kept away by sanitation, &c. Now, if this were the case scarlet fever, which is a very similar disease as regards its infectious properties, would be as rare a disease as true small-pox. This is, however, very far from being the case, and epidemics of scarlet fever are about as common now as ever they used to be.

In sending out the new Order the Local Government Board incloses a circular in which it, in a way, apologises for introducing the Order. It excuses itself chiefly on the ground of economy, and yet in the same breath it says that the remuneration was not excessive. The letter reads:—

> The committee found that, apart from the great increase in the number of operations performed since 1898, the principal factor in the increased cost of public vaccination has been the increase in the fees payable to public vaccinators. But, as the committee pointed out, some increase in the remuneration of the public vaccinators was inevitable, in view of the additional duties which were imposed upon them by the provisions of the Act and of the Vaccination Order, 1898. The committee thought that having regard to the work required the remuneration for primary vaccination since the Act of 1898 came into operation had in many cases not been excessive.

Yet, in spite of all this, it has decided to reduce the fees for primary vaccination by half. This, however, is only a minor point when viewed from the standpoint of public health. It does not appear to me that it will matter greatly to the public vaccinator whether his fees are big or little, as there will be precious few to collect under this *régime*.

There can only be one result if this Order is long in force or the Bill becomes law, and that is that within the next decade the country will be put to the expense of a real small-pox epidemic. But still we must submit, as it is one of the many mandates with which the present Government seems to be over-burdened.—I am, Sirs, your obedient servant,

Chiswick, May 28th, 1907. ARTHUR D. DUCAT, M.B. Lond.

SANITARY AUTHORITIES AND SANITARY OFFICERS.

To the Editors of THE LANCET.

SIRS,—Dr. J. H. Garrett's able and expert critique of modern sanitary government in THE LANCET of May 25th, p. 1447, shows up the defects of the present system. There is, however, another side to the question. The essence of British government is constitutional democracy; let the people rule themselves and find out what they want and find out how to get it. If they blunder on the way no matter; experience teaches. So it is in the matter of public health. Let the people wallow, so says our Constitution, in their insanitary streets and houses, their polluted water- and food-supply, their filthy habits, and general ignorance. They will get their experience; they will compare it with that of their neighbours who take thought; they will have the power to adopt such methods as are proved good and to reject such as are proved bad. They have suffered meanwhile; the helpless in their midst have suffered; but by these very sufferings, altruistic and personal, their responsibility and powers have been realised, and they know they have only themselves to blame. The result is scientifically a compromise—an essentially British institution. Take Dr. Garrett's second alternative—a great central department of government with plenary executive powers over the whole country—a sanitary despotism. Even were this despotism benevolent it would take from the local laity all responsibility and all stimulus to help; it would throw on the central department the burden of each local grievance; it would give fuel for a political conflagration of the most dangerous character. The ten years' story of Indian plague has taught this lesson all too well. The result is lethargy or revolution.

But Dr. Garrett's first suggestion, a revised version of the findings by the Select Committee on the Housing Bill, is more constitutional. As sanitary authority, the committee proposes county councils, Dr. Garrett proposes more uniform districts with committees formed out of existing district councils. I would propose city and county councils, the latter standardised down to areas of a quarter to a half million inhabitants, with local sanitary committees corresponding to the managers of schools. The committee again focus attention on the councils, Dr. Garrett on the officers, and Dr. Garrett would give the appointment of local officers to the Local Government Board. But the Constitution demands that they who pay the piper shall call the tune and that local officers shall be locally appointed. I would suggest appointments by the city and standardised county councils out of a standing list of candidates approved by the Board. Dr. Garrett considers the local council as of secondary importance; I beg to differ. The medical officer of health may on occasion be the leader; he should, as a rule, be the guide. The power and responsibility must always rest with his council and he will effect his object best by convincing them of the lessons of adversity in their own or their neighbours' experience rather than by seeking powers to lead where they will not follow.

Official progress must, then, be stimulated by allowing complaints to be made over the heads of the sanitary authorities to the Local Government Board; by publishing broadcast and outspokenly for the United Kingdom—as by us for our counties—the results of each year's work, not sparing the criticism afforded by figure and fact; and by a very large increase in the Local Government Board inspectorate who should be able to keep themselves in actual touch with the sanitary administration of every part and give sympathy and personal support to every medical officer of health in his now isolated "Aussichtsturm." We are far too much tempted to think of our district as a physician thinks of his patient and consider that the treatment and responsibility for the result are in our hands. This error is a stone wall against which many medical officers of health run their heads and those of their pupils. I beg to raise a voice for constitutional democracy and its application to the sanitary branch of our profession. I am, Sirs, yours faithfully,

FRANCIS FREMANTLE.

Chester-street, S.W., May 25th, 1907.

PRESENT MEANS OF COMBATING SLEEPING SICKNESS.

To the Editors of THE LANCET.

SIRS,—In the admirable article under the above heading in THE LANCET of Feb. 2nd last by Dr. A. Kinghorn and Dr. J. L. Todd there is a point which, I think, may fairly be raised.

In reference to gland palpation it is said: "We have therefore an exceedingly simple method of detecting early cases of human trypanosomiasis which may be applied by almost any intelligent person." This is true as it stands, but it needs the qualification that the stage previous to considerably enlarged glands may well permit the passing of cases even in the hands of the profession. This is rendered the more difficult by the fact that a large percentage of natives from uninfected districts are found on palpation to have slightly enlarged neck glands (viz., 43 per cent. in my hands). I am, Sirs, yours faithfully,

SHEFFIELD NEAVE, M.R.C.P. Lond.

Kambové, Congo Free State.

PULMONARY COLLAPSE AND TUBERCULOSIS: A SUGGESTION FOR PHYSICAL EXAMINATION OF THE THORAX.

To the Editors of THE LANCET.

SIRS,—A short article by Dr. William Huggins on Pulmonary Atelectasis in Adults recently designed to demonstrate that if percussion of the chest precedes palpation it is not unusual to find temporary collapse at the apex of one or other lung. At the time this paper appeared the fact was a familiar one to myself since for many years I had been accustomed to percuss the chest before deep breathing was performed, but so little, if any, attention has been paid to this point and its importance is so great that I am emboldened to bring it forward once again.

The facts are as follows. In a certain proportion of healthy chests examined during quiet breathing and before deep respirations have been taken the apex of the lung is found temporarily collapsed. The signs of this collapse are generally impairment to percussion and feeble breath sounds, these signs disappearing on deep breathing with the production of the dry crackling sounds of expanding lung. The area affected is generally the supraclavicular fossa in front, extending over the shoulder to the supraspinous fossa behind. In more marked cases the collapse may remain for a while in spite of deep breathing and may give rise to deficiency of movement at the affected apex. I have never seen the condition in children (in whom apical phthisis is rare), but closely analogous to it is the temporary collapse of the middle lobe which sometimes occurs in childhood. This, in my experience, is always the accompaniment of bronchial catarrh; it generally persists for weeks and sometimes, I think, becomes permanent and leads to bronchiectasis of the affected lobe. The apical collapse of adults is not necessarily the result of bronchial catarrh, it often occurs in healthy lungs. An estimation of its frequency is very difficult to make, but I believe it may be found in at least from ½ to 1 per cent. of the lungs examined in a hospital clinic.

And now, granting its occurrence, what is its importance? Firstly, it may give rise to errors of diagnosis. Those who palpate before they percuss may find temporary limitation of movement at one apex which may induce an unwarranted suspicion of phthisis. Those, too few in number, who percuss first will find an impairment at one apex whose disappearance after deep breathing may puzzle them unless they are familiar with this condition. The practitioner who omits to demand deep breathing during palpation may find that the lung is not expanded when he comes to auscultate, and crepitations are heard which closely simulate those of early phthisis. These may be temporarily heard in some cases even after deep respiration.

The second point of importance in this apical collapse is the relation it may bear to the localisation of apical phthisis. In a most interesting and instructive paper read by Dr. Arthur Keith before the London Hospital Medical Society in October, 1903, the question, "Why does phthisis attack the apex of the lung?" was discussed from the anatomical standpoint. Dr. Keith shows clearly, among other valuable facts, that the apex of the lung is the part most difficult to ventilate, only slight direct expansion being possible through movements of the first and second ribs, the main expansion being indirect and brought about by movements of the diaphragm. Dr. Keith insists that the diaphragm becomes functionally less active as adult age is reached; he points out that in most of us the lungs are only used to the minimum of their capacity and, he says, "when a shutting-down process sets in the apex is the first to feel it." These contentions of his as to the inefficient expansion of the apex of the lung in adult life are borne out clinically by the occurrence of collapse as already described, and, since this is the main point in which the apex differs from the remainder of the lung, we may conclude that it has much to do with the apical deposition of tubercle. Deficient expansion means sluggish blood and lymph circulation.

And now, having considered shortly the bearings of pulmonary apical collapse on the diagnosis and etiology of phthisis, it behoves us to inquire how our knowledge on these points may be most usefully applied. First, I would like to suggest the advantage of modifying the order of our examination of the lungs. I am persuaded myself, and would suggest it to the consideration of others, that the order—inspection, percussion, palpation, is preferable to the old order—inspection, palpation, percussion. Palpation must be accompanied by deep respiration and I am persuaded that it is best to percuss before this and, if necessary, afterwards as well. The second lesson I would impress upon myself and others is the importance in young adult life of overcoming this tendency to apical collapse and through it to apical phthisis. To this end the lungs should be ventilated at least twice daily by deep breathing and, in those leading a sedentary life, I can think of no more convenient means of accomplishing this purpose than the night and morning use of exercisers or light dumb-bells.

I am, Sirs, yours faithfully,

CLIVE RIVIERE, M.D. Lond., M.R.C.P. Lond.,
Senior assistant physician, East London Children's Hospital,
Shadwell; physician to out-patients, City of London
Chest Hospital, Victoria-park, E.

THE ESTIMATION OF SUGAR.

To the Editors of THE LANCET.

SIRS,—The estimation of sugar by means of a colour test, as described on p. 1446 of THE LANCET, is not new; but it is of great value, as I have proved by a considerable experience of it. The method was introduced many years ago by Sir William Gowers and will be found duly incorporated in the third edition of my "Index of Symptoms," section 679.

I am, Sirs, yours faithfully,

R. W. LEFTWICH, M.D. Aberd.

Buckingham-gate, S.W., June 3rd, 1907.

CALCIUM CHLORIDE ON ROADS.

To the Editors of THE LANCET.

SIRS,—In your issue of May 25th, under the heading "The Chemicalised Road," you comment on the use of calcium chloride for dust prevention and give expression to fears as to the possible injurious effect of the product. We have used this article ourselves during the past 15 years for the prevention of dust on roads in our own neighbourhood and have never experienced any of the ill effects you name. When motor-cars took possession of the high roads in enormous numbers and the dust became an intolerable nuisance we made careful experiments to ascertain what effect, if any, a weak solution of calcium chloride would have on the feet of animals, rubber tyres, metals, clothes, the skin, and so on. We found it had no injurious effect and consequently strongly advocated its use by the public.

We wish to emphasise the fact that we are not dealing with a strong solution of calcium chloride, but with one sufficiently weakened to keep a road free from dust, and with regard to the suggestion that it may attack iron and other metals, as our calcium chloride is absolutely free from acids, its action on metals is no more deleterious than that of a solution of common salt, which, for generations, has been used without harm on roads in the salt districts. Calcium chloride is a *neutral substance*, contains no tar, oil, grease, or other objectionable matter, and *not only does* not injure but positively preserves the surface of a road. The article in your journal has been copied into other public prints, and, unfortunately, has had the effect of making some people nervous about using calcium chloride on roads. In common fairness to the public, who suffer so much from the ill effects of dust, we trust you will give publicity to the facts mentioned in this letter.

I am, Sirs, yours faithfully,
For Brunner, Mond, and Co., Limited,
Thomas H. Forgan,
Northwich, June 1st, 1907. Managing Director.

*** It is quite clear that the results which we mentioned might and would occur if the solution were of sufficient strength—that was surely implied in the article.—Ed. L

THE LESSONS OF THE OUTBREAK OF SMALL-POX AT METZ.

To the Editors of The Lancet.

Sirs,—Much capital is being made by the National Anti-vaccination League at the present time out of the fact that there has recently been some small-pox in Metz, Germany. The *Vaccination Inquirer* for May contains a long article headed in huge type, "Small-pox in the German Empire—Collapse of the Argument from Germany." The argument is this: Germany is a well-vaccinated country; there is small-pox in Germany; *therefore vaccination is useless.*

As you are aware, Sirs, no official report of the outbreak at Metz has yet been published in this country and the *Vaccination Inquirer* gives no information from which it would be possible (assuming its veracity) to draw any conclusions as to the protective effect of vaccination. I therefore wrote privately to Dr. Pawolleck, State medical officer at Metz, asking him for such information. I have received a reply from him which contains the following facts. 1. Since the end of July, 1906, there have been in Metz and the district 164 cases of small-pox, of which 37 have died. 2. No case has occurred since May 12th, 1907. 3. Of vaccinated children under ten not one has been attacked. 4. Of vaccinated children up to 14 one was attacked and had the disease very lightly and very few pock marks were left. 5. Of unvaccinated children up to 14, 22 were attacked, all of whom were very ill, and 12 died. 6. In the town of Metz itself (which Dr. Hadwen of Gloucester has recently described as "the hot-bed of vaccination tyranny") not one child was attacked. 7. In the garrison and outposts, consisting of 24,000 men, no case of small-pox occurred.

It must be remembered that Metz is a frontier town, which may be assumed, in the absence of evidence to the contrary, to have a considerable French population, and to have extensive intercourse with the other side of the frontier. Also that the German vaccination law was passed in 1874, so that all German subjects who are now over 50 years of age had passed their vaccination and revaccination ages before the law was passed and may therefore all be unvaccinated.

I am, Sirs, yours faithfully,
Dorking, June 5th, 1907. J. D. Rawlings.

THE PORTSMOUTH MEMORIAL TO CHARLES DICKENS.

To the Editors of The Lancet.

Sirs,—It is a well-known fact that Charles Dickens, one of the greatest glories in English literature, whose imperishable writings will ever remain among the world's most precious possessions, strictly desired that no statue should ever be erected to his memory. The wish of such a man, however unreasonable it may appear to be, is bound to be respected for all time, but the borough of Portsmouth, where Charles Dickens first saw the light, has at last resolved to raise a permanent memorial to its illustrious townsman in the shape of a cot in the hospital situated in the parish in which he was born. Failing a statue, no happier object could be conceived than this. To accomplish so noble an aim, however, it will, I hear, be necessary to raise the sum of £500. The first £100, and a little over, is already assured, among the subscribers being some of the most distinguished names in the country. There surely ought to be no great difficulty in raising the remainder of the sum required, and I deem it a special privilege and honour to be permitted by the chief promoter of this memorial to make, through the medium of your influential journal, an earnest appeal to every Dickens lover in the land to further this noble object by sending a subscription, large or small, to Mr. C. Louis de Wolff, the indefatigable honorary secretary of "The Dickens Birthplace Fellowship," 73, Laburnum-grove, Portsmouth.

I am, Sirs, yours faithfully,
St. John's Wood, N.W., June 3rd, 1907. Algernon Ashton.

LARGE VESICAL CALCULI.

To the Editors of The Lancet.

Sirs,—Mr. H. Littlewood's letter regarding large vesical calculi which was published recently in The Lancet recalls to my mind a case that came under my notice some three years ago in which a large stone was removed from the bladder by the suprapubic operation. The calculus when dry weighed 16¼ ounces. I was able to follow up the history of the case for 12 months, but then lost sight of the man. A year after the operation he was in perfect health and had no trouble with his bladder. It is of interest to note that it was only a week or two prior to the operation that the calculus caused him inconvenience such as to interfere with his work.—I am, Sirs, yours faithfully,
June 1st, 1907. J. A.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.[1]

(From our Berlin Correspondent.)

The German Congress of Internal Medicine was held at Wiesbaden from April 15th to 18th, Professor von Leyden (Berlin) being in the chair.

The Treatment of Neuralgia.

Professor Schultze (Bonn) described neuralgia as a disease in which fits of pain of great intensity developed within the sensory nerves and followed their track. The nerves might sometimes show certain pathological alterations, but as a rule such lesions were absent. He enumerated the six following causes of neuralgia. 1. Mechanical action, such as compression and tearing. To this category belonged the adhesions between the nerves and the scar which occurred in the stump left after an amputation. It was remarkable that malignant growths, notwithstanding the adhesions associated with them, seldom produced neuralgia. Gallstone colic and intestinal colic were at present believed to be caused by tearing of the nerves of the mesentery and gall-bladder. 2. Neuritis and polyneuritis. These conditions were exemplified in patients suffering from tabes dorsalis, rheumatism, gout, diabetes, infectious diseases, and alcoholism. Neuralgia when occurring as a complication of malaria and of chills was probably connected with neuritis. 3. Psychical influences, hysteria, and neurasthenia. This category included neuralgia due to occupational neuroses and to over-exertion; degeneration or injury of the affected nerve might perhaps be caused by a toxin produced by over-exertion. 4. Toxins either entering the body from outside or produced within it. Neuralgia associated with constipation was an example of this kind. 5. Arteriosclerosis. The connexion between this condition and neuralgia was, however, not yet explained. 6. Anæmia and chlorosis. In these diseases psychical influences were the determining factors of the neuralgia. Professor Schultze said that the pathological anatomy of neuralgia was very imperfectly known as it was impossible to examine the nerves throughout their whole length. In rheumatic sciatica red discolouration of the nerve and slight adhesions have been sometimes observed together with obliteration of the small vessels within the nerves. In neuralgia following amputations Professor Bardenheuer has met with œdema and hyperæmia and Professor Witzel has found cicatrices adherent to the bone. With regard to the symptomatology, Professor Schultze said that points which were painful on pressure might either be present in neuralgia or not; it was necessary to test not only the classical points but also their surroundings and to avoid the use of too strong pressure at the examination. The painful points must not be found by questioning the patient but by observing the occurrence of responses, such as movements of defence, the expression of the face, or even the pulse-rate. Hyperæsthesia or anæsthesia of the skin was often a symptom of neuritis. The diagnosis of genuine neuralgia, such as neuralgia of the fifth nerve or sciatica, was easy; pathological conditions which were very like neuralgia were the meralgia paræsthetica in the fascia lata described by Bernhard, the Achillodynia, which was caused by inflammation of the bursa mucosa situated in the neighbourhood of the tendo Achillis, tarsalgia and metatarsalgia in the metatarso-phalangeal joint of the fourth toe. Sciatica might be confounded with coxa vara, but the diagnosis between them might be made by radiography; other diseases from which it must be distinguished were morbid conditions of the sacrum, flat-foot, and recurrent lameness. In bilateral sciatica, disease of the cauda equina might be present. Neuralgia of the trigeminus nerve was often a symptom of catarrh of the frontal sinus, especially when cerebral and meningeal symptoms were observed. Hysterical and neurasthenic neuralgia differed from the other forms: (1) by the absence of the classical points sensitive to pressure; (2) by the symptoms depending on psychical causes; (3) by recovery following the use of the most dissimilar remedies; and (4) by the pains not following the track of the nerves. Methods of treatment might be divided into the following four classes: 1. The administration of drugs, such as aconitine, strychnine, &c. 2. Physical methods, such as the application of electricity and heat. Using hot air, Professor Bier successfully treated 12 out of 20 cases which had been sent to him to be operated on. Stretching of the nerve merited consideration in cases of perineuritic adhesions, although this operation was sometimes followed by paralysis. 3. Injections of morphine, aconitine, water, air, antipyrine, or methylene blue into the nerve. Dr. Schlösser's method of injections of alcohol has proved successful in four cases under Professor Schultze's care. 4. A surgical operation when all other means had failed. This consisted in a resection of the ganglion as simply cutting the nerve was liable to be followed by relapses. Professor Bardenheuer has completely relieved sciatica in five cases by removing the nerves from contact with bone and embedding them in soft tissue.

---

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medizinische Wochenschrift*, through whose courtesy it has been forwarded to us by our Berlin correspondent.

Dr. SCHLOSSER (Munich) read a paper on the treatment of neuralgia by injections of alcohol. He said that injections of alcohol of 70 or 80 per cent. strength produced a degeneration of the nerves the effect of which was that they became absorbed until only the neurilemma remained. The injection must be made near the point of origin of the nerve, so that as much as possible of the substance of the nerve might be reached. In sensory nerves repeated injections, varying in amount from two to four grammes, must be made; in motor nerves small quantities of alcohol must be injected at intervals of about five minutes. Mixed nerves must be treated like motor nerves, but more energetically. He then gave a detailed account of an injection in a supposed case of neuralgia of the trigeminus nerve. The improvement, as a rule, continued for about a year and the injections must then be repeated if required. When it was doubtful which was really the affected nerve the treatment must be applied to more than one nerve. The use of a general anæsthetic should be avoided during the injection, as the pain indicated the proper point for the injection. Facial paresis might come on after the injections and Dr. Schlösser had seen one case of paralysis of the facial nerve from which, however, the patient recovered in less than three months. Limitation of the motions of the jaws might be produced by the growth of connective tissue between the masseter muscles as a sequel to the injection and might have to be treated by fibrolysin or by massage. He had had under his care 123 cases of neuralgia of the trigeminus nerve and among these a relapse did not occur on an average until after ten months. Among 38 cases of sciatica no relapse occurred in 35 cases; in other patients who were successfully treated without relapse the neuralgia existed in the occiput (16 cases), in the arm (eight cases), in the intercostal spaces (one case), and in an amputation stump (two cases), while in two cases it was associated with tabes dorsalis. Of 11 cases of clonus of the facial nerve nine relapsed after a period varying from three to seven months. Krause's operation gave better results but its mortality was high.

Dr. LANGE (Leipsic) recommended in sciatica the injection of a solution containing 1 per cent. of eucaine and 0·8 per cent. of sodium chloride.

Professor MINKOWSKI (Greifswald) mentioned a case in which sciatica was successfully treated by intraspinal injections of stovaine.

Professor FINKELBURG (Bonn) said that he had made experiments in which alcohol, sodium chloride, cocaine, and other compounds were injected into the substance of the nerve, with the result that paralyses occurred which did not make their appearance when the fluid was injected in the neighbourhood of the nerves. He was of opinion that the majority of observers who have obtained good results from such injections had made them not into the nerve itself but in the neighbourhood of it.

Professor KRAUSE (Berlin) admitted that his operation (the resection of the ganglion of Gasser) was still rather dangerous, the mortality being eight out of 56 cases, but it was the only remedy known in obstinate cases.

Professor BRIEGER (Berlin) reported the results obtained in his hydrotherapeutic institute, where 80 per cent. of the cases of neuralgia recovered.

Dr. SCHILLING said that he had had considerable success by the production of passive congestion according to the method of Professor Bier.

Professor VON NOORDEN (Vienna) said that patients suffering from neuralgia should in the first stage be kept in bed.

Professor SCHULTZE, in concluding the discussion, supported Professor von Noorden's opinion, especially as regards the treatment of sciatica.

The Frequency of Tuberculosis.

Dr. NAEGELI-NAEF (Zürich) said that he had on a former occasion quoted statistics based on necropsies which tended to show that 97 per cent. of the adult population suffered from tubercle to some extent. In opposition to this view it has been argued (1) that in other places a much smaller percentage of tuberculosis was found; (2) that it was not possible to infer the frequency of tuberculosis throughout the population from the number of bodies found to be tuberculous at necropsies; and (3) that in the statistical returns every case of induration has been registered as tuberculosis. Dr. Naegeli-Naef in reply to these objections pointed out that other observers in estimating the proportion of tuberculous individuals among the general population had arrived at results varying from 89 to 94 per cent., which were therefore not far removed from his own estimate. The presence of tuberculosis was completely proved in all the cases which were entered in his statistics as tuberculous.

The Distribution of the Tubercle Bacillus in Tuberculous Subjects.

Professor LIEBERMEISTER (Cologne) said that in examining the bodies of tuberculous patients who had died without general miliary tuberculosis he had found that guinea-pigs became tuberculous when inoculated with the blood or with portions of organs which under the microscope did not show any tuberculous lesion. These organs and the blood must therefore have contained highly virulent tubercle bacilli. This was so in the case of the kidneys, the heart muscle, the nerves, and the veins. This circumstance seemed to show that the tubercle bacillus has a wider distribution throughout the body than has hitherto been supposed.

Pathology of the Œdema of Bright's Disease.

Dr. SCHLAYER (Tübingen) said that he had examined the kidneys after the administration of vaso-constrictor and vaso-dilator compounds respectively. The administration of uranium give rise to the same morbid condition as occurred in poisoning by corrosive sublimate—namely, tubular nephritis. Under doses of a uranium salt varying from 0·1 to 0·3 gramme the normal secretion of urine was arrested, but it was resumed on the administration of diuretics, to be again stopped by the administration of sodium chloride. The essential factor was the nature of the lesion of the renal vessels which in nephritis produced by uranium caused a decrease of the permeability of the kidney, whereas in other forms of nephritis it caused an increase of the permeability. In order to determine the relation of these phenomena to the production of œdema, the subjects of experiment were copiously supplied with water, but no œdema made its appearance until the dilatation of the renal vessels had ceased.

Dr. **Wiesel** (Vienna) said that, according to his observations in chronic Bright's disease, the chromophilic system inside and outside the suprarenal glands was abnormally developed, but only in cases where hypertrophy of the left ventricle of the heart was present. The increase of the chromophilic elements depended on the sympathetic nerves. He was of opinion that nephritic arteritis was due to a degeneration which began in the media of the arteries and led to hyperplasia only after atrophy of the elastic elements and of the muscles had taken place. Nephritic arteritis was anatomically very like arteritis caused by adrenalin.

In the course of the discussion Professor **Strauss** (Berlin) said that vascular lesions were essential for the production of œdema—an opinion which was proved by the clinical fact that after a nephritic apoplexy the paralysed leg remained œdematous for a longer time than the healthy one. A dietary containing a great amount of sodium chloride might cause œdema in patients with Bright's disease because the sodium chloride attracted water. The principal question was the nature of the symptoms from which it might be inferred that a patient suffering from nephritis would probably develop œdema. Professor Strauss was of opinion that this might occur in cases where only a small amount of sodium chloride was present and where the body increased in weight.

Professor **von Noorden** was opposed to the systematic withholding of sodium chloride from patients, because salt-free food was unpalatable and the patients became weaker through having little or no appetite.

The Circulation of the Blood in the Coronary Vessels.

Dr. **Spalteholz** and Dr. **Hirsch** (Leipsic) said that, according to the late Professor Cohnheim, the coronary arteries were end arteries, but by means of injections they had discovered anastomoses between these arteries both in the dog and in the human subject.

Dr. **Schwalbe** (Berlin) said that several other arteries besides those of the heart were erroneously believed to be end arteries.

(To be continued.)

THE RENEWAL OF THE SANDGATE SANATORIUMS SCANDAL.

(From our Special Sanitary Commissioner.)

Once more the Sandgate scandal has come before the public and this in a manner that will cause an unpleasant surprise. The pretence that outdoor treatment such as is given to patients at Nordrach, Davos, and Leysin, could be obtained at the Jones's homes of Sandgate was exposed long ago.[1] Mr. Jones, junior, declared that he had destroyed 10,000 circulars, making assertions to that effect. Committees of the House of Lords and then of the House of Commons inquired into the matter and finally the Sandgate Urban District Council (Sanitary Powers) Act of 1905 received the Royal Assent on August 4th of that year. This law was supposed to herald the dawn of a new era. To Sandgate appertained the honour of having become the pioneer town of Great Britain. It is but a small place with barely 2000 inhabitants, but it is so close to Folkestone as to become practically a suburb of that fashionable seaside resort. This very small community has spent £3000 to get a special Act of Parliament which, as an example, was to prove of great benefit to all towns in general and to Folkestone in particular. From the Jones's homes of Sandgate the undisciplined patients who, for the most part, are suffering from pulmonary tuberculosis, can easily stroll up to the Leas, mingle with the fashionable crowd that gathers on this favoured spot, and listen to the Folkestone band. Doubtless these pauper patients behave as well as can be expected in the circumstances; but there are some rough elements among them, and the inhabitants of Sandgate naturally complain when they find that about one-tenth of the residential population consists of sick paupers imported from other parts of the country and from notably such poor districts of London as are represented by the Poplar Union. Nor are the inhabitants, who treat their own paupers in a very different manner, inclined to believe that the ratepayers of London and other centres would approve of the manner in which their money is spent at Sandgate.

If patients are sent to the seaside at the public expense this is done so that they may be cured by undergoing regular treatment. It is true that in most cases listening to music on the Leas does the patients more good than loitering about the public-houses at Sandgate. The ratepayers of Folkestone, however, are not animated with such loving kindness as to tax themselves so as to provide bands for the benefit of the paupers from Poplar and other such places. Thus at Folkestone, as well as at Sandgate, there was a joyful anticipation that, after an Act of Parliament had been obtained, something more like order and discipline would prevail at the Jones's homes. It was supposed that the patients would be classified and those who were in such a condition as to be a danger to the community would only be accepted in places where there exist private grounds sufficiently large to assure their complete isolation from the general public. The Jones family does possess a property well suited for this purpose—namely, Manor House. It is well away from the town and surrounded by a park and gardens. In regard to its beauty as a private residence this had already been desecrated by the building of pigsties and the attempt to convert an admirable site into a pig farm and dairy. Strange to say, however, that the one and only property which the Jones family possesses which is really suited for the outdoor treatment of tuberculosis is the only place where they have never sent a patient of any description. Moreover, these homes never were under the real and unfettered management of a qualified medical practitioner. It was for this reason that, after a lengthy debate during the congress of the Royal Institute of Public Health when it met at Folkestone two years ago the following resolution was adopted:—

> That homes or sanatoriums for the aggregation and treatment of tuberculous patients should stand in their own grounds in an isolated position away from the general population and be placed under the absolute control of fully qualified medical practitioners.

Formerly it was not reasonable to expect that there should be effective medical control. Before the House of Lords Committee evidence was given and a document was read which did give Mr. A. J. Gore the post of "consulting and acting physician" to the said homes and made him "solely responsible" for the welfare, food, and treatment of the patients. The matrons and nurses who did not carry out his instructions were to be dismissed, and, in fact, on paper the whole arrangement seemed satisfactory. But it also appeared, in evidence, that this deed had been drawn up by Mr. F. T. B. Jones, who was dead, on behalf of his father, Mr. J. J. Jones who was also dead, and was supposed to be applied by Mr. P. H. Jones who had no legal authority whatsoever to deal with the question. Besides, and as pointed out at the time,[2] whatever documents might be drawn up, the medical officer employed could not be really master of the situation. The simple fact of being employed destroyed his freedom of action. The fact that the payments made would not be less than £200 a year and might amount to about £300 placed the medical officer in a dependent position. No medical practitioner would accept such a post if he had sufficient private means to be independent of the remuneration. But, on the other hand, the medical officer would soon discover that he could not keep his post if in his zeal for the welfare of the patients he compromised the profits which his employers derived from the business. Therefore it was felt that so long as such sanatoriums were allowed to be managed on the lines of a commercial enterprise the law should step in between the speculator on one side and the patient on the other and lay down certain principles that must be observed. These rules and regulations of management were not to be left to the medical officer, as he would probably lose his post if he attempted to render them effective. Therefore the Sandgate Sanitary Powers Bill established two very important principles: Firstly, that after March 1st, 1906, no one should keep within the district a building used to receive patients without being licensed; and, secondly, that the district council should draw up rules in regard to the structure and management of such places

---

[1] See The Lancet of August 22nd, 1903, p. 565.

[2] See The Lancet of July 1st, 1905, p. 51.

These rules or by-laws, if approved by the Local Government Board, could then be enforced and penalties inflicted in case of non-observance.

Such an enactment seemed very much to the purpose. It was only necessary for the Sandgate authorities to draw up suitable rules and regulations. As good advice from competent authorities would be readily tendered rules could be drawn up that would render Sandgate free from the grievances from which it had suffered for so long. Other towns seeing how the little community of Sandgate had substituted law and order for the anarchy which had prevailed during many years, would naturally apply for similar powers. Parliament finding such demands flowing in from various quarters would soon conclude that instead of dealing with many local Bills it would be best and would involve less trouble to enact one general law for the entire kingdom. Thus, by its initiative, Sandgate might have taken the first trial step destined to save this country from the slur of having no law to prevent a scandalous exploitation of a large number of patients. If a tradesman wishes to open a shop for the making up of medical prescriptions the drugs must only be handled by a qualified pharmacist. Here, in any case, we have law. But if another tradesman opens a sanatorium for the medical treatment of tuberculous patients, he can construct or purchase the most unsuitable building, he can feed his patients on inappropriate diet, he can overcrowd them, he can lodge them in such a manner as to make it impossible for them to obtain sufficient pure air, he can let them frequent public-houses or music-halls, and, generally speaking, besport themselves in such a manner as to become a danger and a nuisance to the community and greatly to compromise their own chances of recovery. It may pay better, at Sandgate it does pay better, to allow such things to happen than to enforce suitable rules for the care and control of patients. This state of things is pure anarchism—that is to say, there is no law, no government. But at Sandgate it was now thought that law and government would be introduced. The principle was accepted and a law was enacted to that effect. Rules and regulations were to be drawn up and sanatoriums would only be sanctioned if they observed such rules. All this seemed so just, so simple, and so likely to be effected that apparently it was considered too good to be true.

The Lords Committee, it will be remembered, at once set to work to destroy the good which it had done. Events have now proved that this mischievous purpose has been most successfully accomplished, for the law remains a dead letter. The Lords Committee added a clause to the Bill which is worded as follows:—

> If the owner or occupier of any house, building, or premises used as a hospital for disease on the 22nd day of May, 1905, sustains any damage or loss in respect of such house, building, or premises, or in respect of the business conducted in any such house, building, or premises by reason of any regulation made under this Act, or by reason of any condition imposed by the council on the grant or renewal of any licence under this Act, or by reason of the refusal by the council to grant or renew any such licence, the council shall pay to such owner or occupier respectively full compensation for all such damage or loss, and the provisions of the Lands Clauses Acts with respect to the claiming, settlement, and recovery of compensation shall apply with all necessary modifications to compensation under this section.

The term "a hospital for disease," as employed in this Act, is taken to cover homes where tuberculous patients are received and does not include convalescent homes. As it was pointed out at the time, this compensation clause is a premium offered to evil doers. At present anyone who before May 22nd, 1905, established in a crowded London thoroughfare, or in any other unsuitable position, a home for the treatment of tuberculosis may look forward, if the Sandgate precedent holds good, to receive "full" compensation.

It is said that when the Sandgate Bill came before the Committee of the House of Commons a strenuous effort might have been made and that the compensation clause might then have been removed, but there was a risk that this would wreck the entire Bill. At that time the Sandgate district council was anxious to get the Bill in any form, thinking that an imperfect measure would be better than nothing and that it was preferable to pay compensation rather than to allow the scandal of the Jones's homes to continue. It did not reckon, however, on the revulsion of feeling that the disappointment would cause. Here were people the value of whose property and whose incomes had been reduced 50, and even more than 50, per cent. If any compensation was to be given they claimed it for themselves, arguing that the persons who had been ruined should receive compensation and not those who had caused the ruin. Already the impoverished inhabitants heard that their taxes must be increased so as to pay the £3000 which it had cost to carry the Bill through both Houses of Parliament. Now, under this Bill which was to bring them relief they were to be further taxed for the purpose of paying compensation to the Jones family so that they might cease to create a nuisance. Coinciding with this discontent came an election for the renewal of a part of the district council. This election effected a local revolution. The resignation of the clerk of the Sandgate urban district council, who had engineered the Bill through Parliament and was prepared to apply this new law, was now accepted. A new district surveyor and sanitary inspector was appointed. Of the three most important local functionaries only the medical officer of health remained. With the new men came a new policy which has led up to the recent proceedings and judgment against the Jones's homes before the Elham county bench. This result, however, was not obtained under the new law but under the old Public Health Act of 1875. All the difficulties that for so long afflicted the inhabitants of Sandgate are of more than local interest. In the absence of any law on the subject similar difficulties may arise in any part of the country. Therefore it is of practical utility to understand in its principal features the problem as it now stands. For this purpose it will be necessary to analyse the details of the proceedings which have taken place and to examine carefully the situation created by the new Act of Parliament.

SOME TURKISH LAZARETS
AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.

(With Reproductions of Photographs taken by the Author.)

VI.[1]

THE CAMARAN LAZARET (*continued*).

Existing Hospitals for Infectious and for Ordinary Diseases.—Inadequacy of Present Buildings (Arishes).—Statistics of Ordinary Sickness among the Pilgrims.—Proposed New Hospital for Ordinary Diseases.—History of Plague and Cholera at Camaran since 1890.—Proposed New Hospital for Infectious Diseases and Small Disinfecting Pavilion common to the Two Hospitals.—The Personnel of the Lazaret: Permanent Staff and Annual Mission; the Accommodation Provided for Them.—New Houses Proposed for the Medical Officers and for Several Minor Employees.

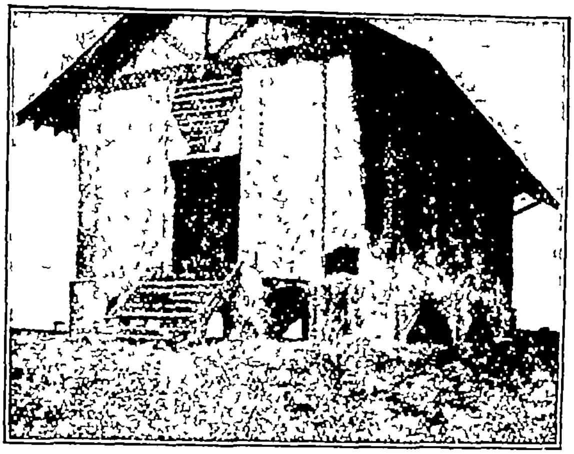
THE present hospital accommodation at Camaran is not of a very satisfactory character. As already stated, it was originally intended that the sick should be treated within the cordons, instead of being removed to a central hospital; and with this object a masonry building was constructed in (or near) each cordon. The characters of these buildings were briefly described in Article IV. They are built of bricks prepared at Camaran; the flooring is raised and supported on a series of arches and piles, also composed of brick. Unfortunately the bricks have proved to be not sufficiently strong to support the weight of the buildings. In each of them, with a quite remarkable uniformity, the walls have become badly cracked, and there is a serious outward thrust at the junction of the basement and the walls. In addition, the flooring, composed of tiles, has been badly distorted; the two rows of tiles corresponding to each row of brick piles underneath have been crushed together (like the angle of a roof); and the brick arches threaten to fall in. In one of the buildings (that at the fourth cordon) this has actually happened: one arch has entirely collapsed and a gap a yard or more wide runs right across the floor of the building. The exterior of one of the camp hospitals is seen in Fig. 22. The Commission, on the advice of its engineer, condemns these "hospitals" as too dangerous to be put to any use and recommends their demolition. Some of the material of which they are built (notably the woodwork and tiles of the roofing) can be employed for other constructions.

---

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of April 27th (p. 1188), May 4th (p. 1251), 11th (p. 1317), and 18th (p. 1389), and June 1st (p. 1518), 1907, respectively.

For some years past it has been recognised that it is more satisfactory to treat the sick in a central hospital than in the cordons themselves. Two temporary hospitals composed of "arishes" have been run up, one on the small island already mentioned near the third cordon and the other some way inland and near the oasis and Sheikh Iraki's tomb. The hospital on the small island consists of two mat sheds; it is occasionally used to isolate cases of small-pox. The sheds are old and in bad condition, and this "hospital," which, as the Commission states, scarcely merits the name, is condemned to disappear. The other hospital consists of three arishes, of practically the same construction as an old-type arish for pilgrims in the cordons but rather smaller. It is surrounded by a lath fence and connected with the rest of the lazaret by a branch of the Décauville railway. The arishes were originally put up to lodge the military guard of the lazaret and have only been used as hospital wards since 1902. The interior of one is seen in Fig. 23. Each arish can hold 12 patients. At the end of one is a small compartment used as a laboratory; and there are other sheds used as a kitchen and offices. Outside the enclosure there are two pits in the sand into which the excreta are thrown and covered with lime. In place of this hospital, which does not fulfil the requirements of a modern institution of this nature, the Commission proposes to build a masonry hospital for ordinary diseases, the plan of which is annexed to its report. This plan provides for four wards, in separate pavilions, two of which would hold 12 patients each and the other two eight patients each. There would thus be accommodation for 40 patients. Experience has shown that this will suffice for the needs of the lazaret; indeed, up to the present the total number of sick under treatment at the same time has rarely exceeded 30. The following table shows the numbers of sick pilgrims removed to hospital in the last three pilgrimage seasons.

FIG. 22.



Hospital in one of the cordons.

FIG. 23.

Interior of a hospital arish.

Year.	Number of sick.			Number of cases of small pox.
	Men.	Women and children.	Total.	
1903-4	164	52	216	12
1904-5	120	24	144	29
1905-6	168	27	195	13

The plan of the proposed hospital further provides for an operation-room, a bacteriological laboratory, a kitchen, a pharmacy, and rooms for attendants and for linen, &c. Surgical cases are not very common among the pilgrims but they do occasionally occur and, in addition, cases requiring operation are not infrequently attracted to the Camaran hospital from among the Arab population of the island and of the mainland. Lithotomy or lithotrity and amputation for mycetoma (Madura foot) are the operations most frequently performed. I have published elsewhere[2] what are, I believe, the first recorded observations on the existence of the last-named disease in Arabia. As far as they go, they would seem to show that Madura foot is of quite common occurrence in the Yemen province of that country.

In addition to the hospital for ordinary diseases the Commission strongly urges the construction of another hospital for infectious diseases, especially plague and cholera. It is, indeed, one of the most serious deficiencies in the lazaret as it now is that there is no proper accommodation for the isolation and treatment of cases of these diseases. Fortunately, of recent years neither plague nor cholera has been very frequently seen at Camaran, but it is obvious that they may occur at any time and that means should be provided for promptly dealing with them if they should break out. The history of both these diseases in the Camaran lazaret during the last 16 years is of considerable interest and may be briefly summarised as follows. Accurate records for the years preceding 1890 are unfortunately wanting.

In 1890 the s.s. *Deccan* arrived at Camaran from Bombay, having had 34 deaths on board during the voyage, seven of which were ascribed to cholera. There were three cholera patients on board at the time of arrival; 12 other cases developed during the landing operations; and in all there were 36 deaths from the disease among the pilgrims from this ship. The rest were detained 59 days in the lazaret. In addition, a soldier on guard, three Arab "gardiens," the "*bakal*" (provision seller), and three inhabitants of the village died from cholera which was therefore the cause of 44 deaths in all. Two other infected ships arrived at Camaran the same year on their way back from the Hedjaz (already invaded by cholera); on one there were four cases and three deaths, while on the other there were 11 cases and six deaths.

In 1891 the s.s. *Sculptor* arrived at Camaran on May 1st. Nothing suspicious had occurred during the voyage. On the 8th cholera broke out among the pilgrims from this ship and up to the 21st there were 18 cases and 14 deaths from the disease. In addition, an Arab guard died from cholera. In the same year one fatal case of cholera occurred among the pilgrims returning to the Yemen from the Hedjaz.

In 1893 the s.s. *Adana* arrived at the lazaret, carrying soldiers from Hodeidah, the principal port of the Yemen. Cholera was then present in that province. The disease attacked the men in the lazaret and caused 37 deaths. The ship remained 39 days at Camaran. In the same year a suspected case of cholera occurred on the voyage and another at the lazaret among the passengers of a ship from Calcutta. In May of the same year the s.s. *Knight of St. John* arrived at Camaran; cholera broke out amongst the passengers three days after they had landed in the lazaret. There were in all 34 cases with 25 deaths. The ship remained 31 days in quarantine.

In March, 1895, the s.s. *Mohammadi* arrived at the lazaret with 818 pilgrims. On the seventh day after the landing of the latter cholera appeared and in 17 days was the cause of 27 cases and 25 deaths among the pilgrims. In addition a native employed in emptying the cesspools and three soldiers died from the disease, bringing the total number of cases to 31 and of deaths to 29. In the same month of the same year the s.s. *Jubeda* arrived with 1044 pilgrims. Four days later cholera broke out amongst them and in the course of a month 57 pilgrims were attacked by the disease and 48 died; in addition six guards and two soldiers died from it. There were thus in all 65 cases and 56 deaths from cholera. In April, 1895, the s.s. *Husseinee* arrived at Camaran with 706 pilgrims. Six days later cholera broke out amongst them; the epidemic lasted a month and caused 20 cases with 15 deaths among the pilgrims and one death among the Arab guards.

---

[2] Brit. Med. Jour., April 21st, 1906.

Since the date last given no case of cholera has been observed in the Camaran lazaret. It is certainly a striking fact that, while in the first five years of the series, cholera was imported there on 11 occasions, in the last 11 years it has not once made its appearance. This difference is probably to be ascribed to the stricter measures taken in Indian ports before the departure of pilgrims since the appearance of plague in Bombay in 1896, and also in some degree to improvements effected in the lazaret itself—more particularly the introduction of steam disinfecting stoves and of a distilling apparatus to provide a pure drinking water. The only case of plague observed at Camaran during the period under review was an imported case which occurred on a sailing ship in 1900; the patient recovered.

The Commission's report expresses the hope that the lazaret may continue to be as free from cholera and plague in the future as it has been in the past 11 years. But, as is rightly pointed out, either disease may appear there at any moment and it is the first duty of those responsible to provide a proper hospital for the isolation and treatment of such cases as may occur. The Commission proposes therefore the construction of a small hospital of three wards, in separate pavilions, each ward sufficing for eight persons. The plan of such a hospital, with its annexes, is inserted in the report.

Each of the two hospitals proposed by the Commission will be surrounded by a high wire fencing of the same character as that proposed for the cordons. The hospital for infectious diseases will be built at some distance to the north of the hospital for ordinary diseases. Between the two it is proposed to build a small disinfecting pavilion for the common use of both, and to establish here the moveable disinfecting stove of which mention has already been made. The new hospital sections will be connected with the rest of the lazaret by a loop line of the Décauville railway.

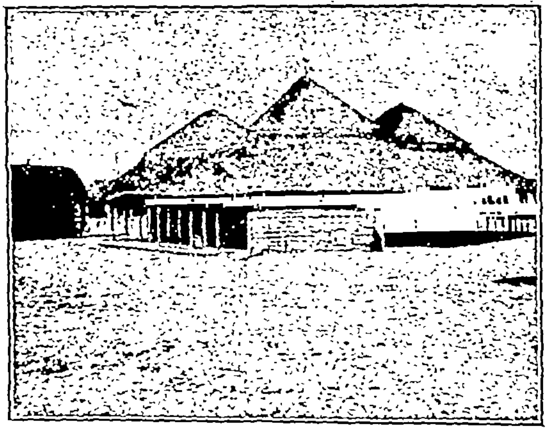
In the preceding articles I have described at considerable length those portions of the lazaret of Camaran that are essentially intended to serve the needs of the pilgrims themselves. There remain, however, a large number of buildings and installations connected with the administration of a large institution such as the one in question. These may be somewhat more summarily dealt with.

The staff of the lazaret and their residences.—The staff is made up of two groups of employees—those who remain at Camaran all the year round (*personnel permanent*) and those who go there only for the five or six months of the pilgrim season (*personnel provisoire*). The latter form what is commonly spoken of as the annual "mission" to Camaran. The permanent staff consists of the director (a medical man), a first clerk, a first kiatib (Turkish clerk), a "magasinier," three disinfectors, first, second, and third engineers (*mécaniciens*), two assistant engineers (*aide-mécaniciens*), a stoker, two painters, two masons, a carpenter, two head guards, eight guards, a "chef-arichdji," and eight "arichdjis" (i.e., builders of arishes), two boatmen, and some other employees. The "mission" consists of from seven to ten medical men, a lady practitioner (from India), a chemist, a second clerk, two additional disinfectors, two additional boatmen, three male and one female hospital attendants, and others. In addition to the above there is the crew of the tug, consisting of a captain, an engineer, a stoker, and three sailors, and a large and variable number of Arabs and Dankalis, employed as "guards" in the cordons, to assist in the machinery building, in the disinfecting pavilions, or in the emptying of the excreta pits (*vidangeurs*), as postmen, messengers, servants, and in a variety of other capacities. The number of "guards" employed varies with the number of pilgrims interned in a given cordon. In principle there should be one guard for every ten pilgrims, but this maximum is rarely attained. Still there are often 30, 40, 50, or more guards in a single cordon; they are paid from four to five piastres (8*d.* to 10*d.*) a day. A considerable number of the persons mentioned in the above list live in the village of Camaran. The rest (including all the European members of the staff) are housed at the lazaret in a series of structures which may be briefly described as follows.

In each cordon is the "doctor's house" mentioned in Article III. It is proposed, as there stated, to give up these houses to pilgrims "of distinction" and to build a new smaller house for the medical man in each camp. The plan of such a house is annexed to the Commission's report; it provides for two rooms, with a good verandah back and front, and kitchen, bathroom, and water-closet (all lacking in the present houses) attached.

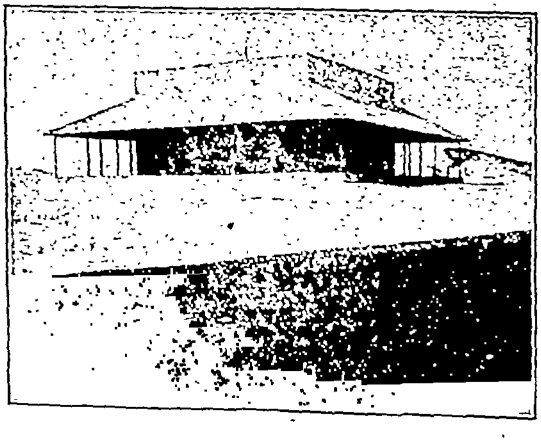
When not on duty in the cordon the medical members of the staff are mostly lodged in rooms in the upper storey of a building known as the *logement du personnel*. This is the largest and most central of the administrative buildings. It contains the offices of the lazaret and a large store-room on the ground floor and was intended originally to have no upper storey. But, as an after-thought, the upper storey was added with a verandah running round it. A number of "kutcha" constructions, used as kitchens, depôts, &c., in its immediate neighbourhood are condemned to disappear.

FIG. 24.



New arish-bungalow occupied by the Commission.

FIG. 25.



The lady practitioner's house.

As a whole, the building is of solid construction and in fair condition; it has certain defects which it is proposed to remedy but which scarcely need to be enumerated here. The rooms in the upper storey serve to house not only the medical officers of the lazaret but also some other members of the staff. The Commission proposes to build a separate house for the medical officers, the plan of which is furnished in its report. It would provide for a large common room, six bedrooms, two deep and shady verandahs, kitchen, bathrooms, and water-closet.

Fig. 24 is a view of the arish-bungalow built for the members of the Commission and occupied by them during their stay in the island. It will henceforth serve as the residence of the director of the lazaret and his family. It is built of the same materials as the arishes for pilgrims, only of rather better quality, and the whole has been more carefully constructed. It consists of a central dining-room of hexagonal shape, with three bedrooms and three deep verandahs leading off it. In the climate of Camaran it made a pleasant, cool, and shady house to live in.

The lady practitioner, who comes to the lazaret from India each pilgrimage season, occupies a stone house specially built for her and only recently finished. It is seen in Fig. 25 and is one of the most satisfactory of all the residences provided for members of the staff. In another stone house, at no great distance, is lodged the British Vice-Consul, who comes over from Hodeidah to reside at Camaran during the pilgrim season. On the "Mervani plain," close by, are five small houses occupied by different employees of inferior rank. They were originally built as temporary lodgings for the workmen employed in the repair and completion of the lazaret ten years ago. The Commission found them unsuited for permanent residences in a climate such as that of Camaran, and it is proposed consequently to build five houses in their place, not on the same site but on a hill close to the northern shores of the bay, known as the Djebel Hadlja. This hill rises some 40 or 50 feet above sea-level and is one of the most airy and pleasant spots in the island. Finally, there are several arishes, some on Djebel Hadlja, some near the machinery building and elsewhere, occupied by the guards and other inferior members of the staff.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Schools as "Poison Dens."

IN the course of a discussion at a recent meeting of the Cheshire education committee some strong language was used as to the insanitary condition of many of the schools in the county. The matter arose from the Director of Education drawing the attention of the committee to the fact that the Government grants to elementary schools were liable to reduction on account of the absence of children from school either suffering from infectious sickness or coming from homes where it existed. One of the members said that some of the schools were "simply poison dens where children were crowded to the prejudice of their health. When they were poisoning the children it was no wonder they had epidemics." In the face of this statement, which does not appear to have been contradicted, it was decided to ask the Board of Education to compensate education authorities for any loss of grant owing to the absence of scholars on account of infectious disease. If the condition of some of the schools is as bad as described, and the educational authorities allow it to continue, they are asking for compensation for loss of grant due to the insanitary state of schools under their authority, for which conditions they are responsible. Their obvious duty is to get rid of the insanitary conditions and afterwards ask for compensation.

The Rearing of Infants.

Mr. A. W. Martin, the medical officer of Gorton, has been speaking some plain words in his report as to the prevalence of diarrhœa among the children during the latter part of last year. He states that of the number of cases only about half the mothers had made an attempt to suckle their infants. "The present generation is witnessing an occurrence in evolution never probably before experienced by the human race, and that is, a race of breastless women." He says it is difficult to estimate the extent of the connexion between this and the increased drinking habits of women, but he believes it has an important bearing on it. The evolution he speaks of is not an agreeable one, independent of its being of ill omen for the coming race.

Death from Anthrax.

Two butchers, living near Blyth and working for the Seaton Delaval Coöperative Society, developed symptoms of anthrax on May 23rd. One of them has died at the Newcastle-on-Tyne Infirmary, but the other is said to be going on favourably.

June 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Military Hospitals in Scotland.

THE War Office recently approached the St. Andrew's Ambulance Association to see whether it could, in case of war, take charge of the military hospitals in Scotland and so release the Army Medical Corps for service abroad. I understand that the association has expressed its willingness to undertake the duty. It has been arranged that the officers and men in time of war would receive payment on a similar scale to that in force in the Royal Army Medical Corps and would have to hold themselves ready for service at 48 hours' notice.

Industrial Diseases in Glasgow.

In connexion with the evidence taken by the Departmental Committee on Compensation for Industrial Diseases the information given by Dr. A. K. Chalmers, medical officer of health of Glasgow, was distinctly interesting. The death-rates from these diseases when in tabular form bring out very clearly the diminution in the number of deaths from the various so-called industrial diseases. From all causes for males and females at each decennium the rates are now lower than in the 1871 period, and, as a rule, the male rate is in excess of the female rate save between the ages of 25 and 35 years. As regards pulmonary tuberculosis in the "seventies," the female rate exceeds the male rate at each age period and is still above it at ages from 25 to 45 years in 1902; from 45 to 65 years it is below it. As regards other respiratory diseases, the female rate is uniformly lower than the male rate throughout. As some inequalities appeared in the tables when pulmonary tuberculosis and other diseases of respiration were shown separately it was thought well to group all diseases of the lung, including pulmonary tuberculosis, together. The result was to produce a more uniform movement in the rates and showed that between the ages of 25 and 35 years those for females were almost always, although only slightly, in excess; but in the succeeding decennial periods, and particularly after the age of 45 years, the reverse was the case and became pretty marked.

Arbroath Infirmary.

The honorary treasurer of the Arbroath Infirmary has received a cheque for £100 to go to the funds of the infirmary from the North British Railway Company in recognition of the services rendered by the infirmary at the time of the Elliot Junction disaster.

Motor Ambulance Vans and Speed Limit.

At Kilmarnock sheriff court last week the driver of a motor ambulance was charged with exceeding the ten-mile limit in passing through the village of Fenwick. The defence was that a motor ambulance was privileged in the same way as a fire brigade, and the driver stated that he had never been interfered with in Glasgow or elsewhere when exceeding the limit. In this case the ambulance was empty but the driver was hurrying back to take a patient to the infirmary. The sheriff, in imposing a modified penalty of £1, said he should be inclined to regard with great consideration any ambulance van or fire engine which was proceeding for the preservation of life or property, but it would be a very curious way of promoting the public safety if ambulances were to go at such a rate as to cause people to be killed or accidentally run down.

Asylum Tragedy.

A most unfortunate incident is reported from Sunnyside Asylum, Montrose. In a dormitory where several men were sleeping was one old man, 68 years of age, who was partly paralysed. During the night he was attacked by the patient in the next bed to him and died from a wound inflicted on the head with a wooden chair. No blame is attached to the hospital authorities as the assailant had previously shown no homicidal tendencies.

Heavy Infantile Mortality at Stirling.

The Stirling town council has decided to appoint a lady as health visitor and nurse in view of the alarming infantile mortality prevailing in the poorer districts of the town. The mortality last year among infants was 212 per 1000—a number exceeding the infantile death-rate in even one of the lowest and poorest localities in Glasgow.

University of Aberdeen: Cancer Research Fellowship.

At a meeting of the Senatus of the University of Aberdeen held last week, the Medical Faculty reported that an appointment had now been made to the Fellowship for Cancer Research recently instituted in the University by the Hon. A. McRoberts, the gentleman appointed being Mr. Bertie R. G. Russell, M.B., Ch.B. Aberd., who is at present practising at Ilford, Essex. The value of the Fellowship is £200 per annum. Dr. Russell was winner of the Anderson research scholarship in connexion with the University of Aberdeen.

Great North of Scotland Railway Ambulance Competition.

The eighth annual competition for the silver challenge cup presented by the directors of the Great North of Scotland Railway Company for the team most proficient in ambulance work was held on Saturday of last week at Inverurie under the auspices of the St. Andrew's Ambulance Association. The competition is open to teams of five men each drawn from the servants of the company and the Joint Station Committee who have gained ambulance certificates or hold medallions of proficiency in the work. Four teams entered—Aberdeen Guards, Elgin Station, Locomotive No. 2, and Locomotive No. 1. The result was as follows:—

	General knowledge.	Bandaging, &c.	Transport.	Total
1. Locomotive No. 2	77½ ...	83 ...	82½ ...	243
2. Aberdeen Guards	76½ ...	75 ...	84 ...	235½
3. Locomotive No. 1	71½ ...	74 ...	87½ ...	233
4. Elgin Station	75 ...	75 ...	78 ...	228

It may be mentioned that since the inauguration of the competition in 1900 the locomotive department has gained the cup five times—namely, in 1900, 1901, 1904, 1906, and 1907, while the Aberdeen guards were successful in 1902, 1903, and 1905.

June 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Public Health of Belfast.

AT the last weekly meeting of the Belfast health committee, held on May 30th, it was reported that there were 22 cases of cerebro-spinal meningitis notified for the week ended May 25th, as compared with 24 in the previous week, the total cases up to the date named being 465 and the total deaths 336. The cases recently admitted are of a milder type. The Registrar-General, Mr. Robert E. Matheson, has issued a special return relative to the epidemic for the quarter ended March 30th which gives some interesting statistics with regard to age and sex incidence. During the week ended May 25th the death-rate of Belfast was 23·1 per 1000, and during the four weeks ended at that date there were 221 notifications of infectious disease.—At the usual monthly meeting of the Belfast city corporation, held on June 3rd, it was reported that between April 14th and May 18th the general death-rate of Belfast was 23·7. The report of the medical officer of health was largely statistical, but a comparison of Belfast with smaller Irish towns like Cork, Limerick, and Londonderry is unfortunate. The bolder lessons to be drawn by comparison with towns of equal size in England and Scotland should be given to the population. The complete scheme for the new asylum put forward by the chairman of the asylum committee has been dropped on the ground of expense, and preliminary plans are to be prepared for extensions at Purdysburn to consist of administrative buildings, places of worship, and four additional villas.

Queen's College, Belfast.

It will be recollected that about a year ago Sir Donald Currie, who gave the munificent sum of £20,000 to the equipment fund of Queen's College, Belfast, in reply to a request from the students, promised also that, if by June, 1907, a sum of £3750 was raised he would contribute £1250, so that £5000 might be available for an athletic ground adequately equipped. The students thought that the best plan was to organise a great fête, and this was opened on May 30th by Mrs. Wisely, a daughter of Sir Donald Currie, and it has been in full swing every weekday until the evening of June 3rd. Unfortunately, the weather was most inclement and interfered with the outside "shows," but it is hoped that the desired sum will be raised to fulfil Sir Donald Currie's offer. The students and their friends worked very hard to make the fancy fair a success.

The Weather.

During the past week the weather in the North of Ireland has been very severe, cold, wet, and stormy, so that up to the present there is no appearance of summer.

June 4th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Infantile Mortality in Newport.

THE question of infantile mortality has for some years occupied the attention of the sanitary committee of the Newport (Mon.) corporation. During the five years 1896–1900 the infantile mortality rate in the borough was 170 per 1000 births and in the five years 1901–05 it was 142 per 1000. These figures show that the efforts made by the sanitary authority to reduce the mortality have not been without effect. It is of interest to note that water carriage is almost universal in Newport, so that there has been no abolition of privy middens, to the existence of which in the midland and northern towns the large amount of infantile mortality is so often attributed. In a recent exhaustive and instructive report the medical officer of health (Dr. J. Howard-Jones) points out that the chief measures by means of which the amount of child mortality may be reduced include (1) the education of the expectant mother in respect to the great importance of attending to her personal health and of making every effort to bring up her child at the breast; (2) education of the girls in the higher standards in domestic hygiene and temperance and the formation of continuation classes in these subjects; (3) the notification of all births within 48 hours to the medical officer of health; (4) measures for the better protection of infants, such as the strict supervision of illegitimate and farmed-out children; (5) measures operating through the mother, such as the feeding of expectant and suckling mothers; (6) measures for providing a pure milk-supply for hand-fed infants; and (7) measures for promoting cleanliness outside the homes. Dr. Howard-Jones considers that in the past too much attention has been paid to the provision of pure milk depôts instead of obviating the necessity for them by inducing mothers to nurse their offspring. He suggests that the midwives in practice in the town should be asked to coöperate in the work of persuading their patients to adopt breast-feeding and that there should be an organised system of visitation of the mothers for the purpose of educating them in regard to infant and domestic hygiene.

Cardiff Police Surgeons.

The Cardiff corporation has decided not to appoint a chief surgeon to the city police. A recommendation to make such an appointment was made last year by the head constable who proposed that the duties of the surgeon should be to examine all recruits for admission to the police force and to the fire brigade, to examine and to report upon cases of constables recommended for temporary pensions in consequence of incapacity, to deliver ambulance lectures and to consult with the divisional surgeons in cases of suspicious death where a second opinion was required. Until 1901 there was only one police surgeon in Cardiff but early in that year three surgeons were appointed, each with a separate division.

Notification of Pulmonary Tuberculosis in Shrewsbury.

The Shrewsbury town council has resolved on the recommendation of the medical officer of health (Mr. M. Gepp) to adopt a system of voluntary notification by the medical practitioners in the town of cases of pulmonary tuberculosis and to offer to disinfect, free of cost to the occupier, every house which has been vacated by a consumptive patient.

(FROM OUR OWN CORRESPONDENT.)

The Early Reaction of the Skin in Radiography.

AT the Academy of Medicine on May 22nd M. Béclère pointed out that in working with the x rays or salts of radium the inflammatory reaction generally takes ten days to appear; sometimes, however, on the second day an early and irritating erythema comes out which may be called the "pre-reaction." This is due to the less penetrating "secondary" radiations given out from the glass wall of the Crookes tube or the metallic envelope of the radium salts. From the therapeutical standpoint the chief lesson to be learnt from this physical theory is this, that the radiographer who wants to know if he has reached or exceeded the proper time of exposure and if he should continue the treatment should not, as is generally held, be guided by the presence or absence of this early reaction which is a purely accidental phenomenon, but should study as accurately as he can the necessary time of exposure to the therapeutic agent that he uses, whether the Roentgen or radium emanations; this is the best method of estimating the degree of the regular reaction which will follow and which is alone of importance.

Treatment of Ozæna by Injections of Solid Paraffin.

At the Congress of the French Otological, Laryngological, and Rhinological Society on May 14th M. Gault showed a paraffin syringe which was very simple and ingenious. Instead of increasing the force, which is the principle adopted in Broeckaert's apparatus, Gault's instrument decreases the resistance. It consists of a long body and short needle, and with it cylinders of solid paraffin at 45° C. can be injected; it is simple, light, easy to sterilise and to manipulate, and should prove very serviceable in the marked atrophic cases where injection has proved difficult.

Lumbar Puncture in the Treatment of Syphilis.

M. Jeanselme and M. Barbé have shown by performing lumbar puncture on 53 cases of syphilis that lymphocytosis may appear at any stage of the disease; it occurs frequently in the secondary eruptive stage but is not regularly found. It may equally well be seen in old cases with no nervous lesion that can be detected clinically. When a lumbar puncture can be done after a course of mercurial inoculations the continuance or disappearance of the lymphocytosis gives a useful indication as to whether the treatment should be continued or not; in fact, it replaces a guesswork system by a rational method of treatment.

Predisposing Effect of Cold in Experimental Tetanus.

On May 18th at the Biological Society M. Ciuca gave an account of some recent experiments with regard to tetanus. He first reminded his audience that the subcutaneous injection of tetanus spores which have been heated to 80° C. is innocuous, and that M. Vincent has shown that exposing the inoculated animals to excessive heat suppresses their resistance and determines the appearance of general tetanus. M. Ciuca has arrived at analogous results by submitting mice to cold. Immediately after being exposed to a temperature of 2° C. for one hour they were each injected with ¼ cubic centimetre of tetanus culture eight days old that had been heated to 80° C. for an hour. After four days tetanus developed and immediately became general and the animals died in 16 or 20 hours. Controls inoculated with the same dose without being exposed to cold showed no sign of tetanus. The same general tetanus occurs when the inoculation with heated spores is done not before but just after the exposure to cold. To sum up, chilling mice as well as overheating them abolishes their resistance to the inoculation of heated tetanus spores.

The Prophylaxis of Scarlet Fever.

At a recent meeting of the French Society of Military Medicine M. le Rouvillois said that he had ascertained that most of the epidemics of scarlet fever in military centres were due to infection brought by soldiers returning from their New Year's leave. These epidemics occur most frequently during the month of January and it would therefore appear that if the New Year's leave were stopped it would be a valuable prophylactic measure.

Poisonous Gases in Wells.

Only recently five workmen lost their lives by gas poisoning in descending a deep well. At the meeting of the Academy of Medicine held on May 21st M. Gréhant reminded his hearers that some time ago he had recommended a very simple method of preventing these lamentable accidents. It is only necessary before the men go down to lower a cage containing some small animal, such as a guinea-pig or a rabbit. If the animals die it shows that the air of the well is irrespirable by human beings.

Obituary.

Dr. Féré, whose death was recently announced, was a neurologist whose attention was at the beginning of his career directed towards surgery. The influence of Charcot, however, and the light which he threw upon the pathology of nervous diseases, attracted Féré into a different path. Early in his professional life he was appointed physician at Bicêtre where he remained to the end of his days. He was a man of wide research and of flexible intellect while he wrote much. His chief published works were "The Pathology of the Emotions," "The Neurotic Family," "Degeneration and Criminality," "Animal Magnetism," "The Evolution and Dissolution of the Sexual Instinct," "The Various Forms of Aphasia," and "The Home Treatment of the Insane" (*dans les familles*). His researches into the subjects of teratology and experimental teratogeny were a marked portion of his life's work and will be the means of keeping his memory green in the scientific world.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Use of Tuberculin as a Test for Tuberculosis in Children.

AT a recent meeting of the Berlin Medical Society Dr. von Pirquet of Vienna read a paper on the Diagnosis of Tuberculosis in Children by Cutaneous Inoculation of Tuberculin. He said that after vaccination the reaction leading to immunity became visible as a rule on the second day and was fully developed within a week. Similarly, after the cutaneous inoculation of tuberculin a small papule was formed on the skin and disappeared within a week. In children under two years of age this reaction showed itself only in the case of those who were tuberculous, but at more advanced ages all children, whether tuberculous or not, showed the reaction, so that after two years of age the presence of tuberculosis could not be concluded from its occurrence. After inoculation 88 per cent. of the tuberculous children under two years of age showed the reaction, while 12 per cent. did not show it, the latter being either in a cachectic condition or suffering from miliary tuberculosis. Post-mortem examinations, which had been made in 23 cases, proved that the reaction occurred in the overwhelming majority of tuberculous children and that it was absent in non-tuberculous children. The reaction in question was a purely local manifestation, unattended by general constitutional symptoms, so that immunity was not produced.

Nephrectomy for Tuberculosis of the Kidney.

Professor Israel at a recent meeting of the Berlin Surgical Society gave an account of the after-history of the patients on whom he had performed nephrectomy for tuberculosis of the kidney. For this disease he had performed 102 operations, of which four were nephrotomies and one was a resection, the remaining 97 being cases of nephrectomy, which was of course the standard operation in the circumstances. Of the above 97 cases 11 died from the operation, ten died afterwards, and from three no replies to inquiries were obtained, leaving 73 patients whose subsequent history could be followed. In 45 of these 73 the operation was performed between two and 15 years ago, so that a definite opinion as to the results could now be formed. The patients were examined as to their weight, their general state, the function of the bladder, the possible existence of tuberculosis of the bladder, the quality of the urine, the state of the other kidney, and the cause of death in the case of the deceased. The result was that the patients had increased in weight by amounts varying from five to 45 kilogrammes, the average gain being 18·7 kilogrammes. Their general state was described in 86 per cent. of the cases as being very good, in 5·7 per cent. as tolerably good, and in 7·6 per cent. as weakly. It was proved by the investigation that nephrectomy when tuberculosis of the bladder was also present had a salutary effect on the latter condition, and from this fact it might be inferred that the disease began in the kidney and descended to the bladder. The symptoms connected with the bladder consisted in pain and in frequent micturition. The pain was relieved by the operation, so that *80 per cent. of the patients had no pain after it.* The frequency of micturition, which in 85 per cent. of the cases was abnormally high, became so much less that after the operation it was normal in 60 per cent., while in 11 per cent. more a considerable improvement followed, so that 71 per cent. of the patients were distinctly benefited by the operation. In two cases of bilateral tuberculosis of the kidney no improvement was obtained. The causes of the cystic troubles in tuberculosis of the kidney were not the same in the normal and in the tuberculous bladder respectively. In a normal bladder these troubles arose from the kidney by irritation caused by the secretion of the affected kidney and they disappeared immediately after the removal of that kidney. In a tuberculous bladder, however, the improvement depended on a diminution of the tuberculous process therein, as might be proved by cystoscopy and by the disappearance of tubercle bacilli from the urine. The improvement of the cystic troubles took place much later than in a healthy bladder and corresponded with the extent of the tuberculous process within the bladder. If only a small portion of the bladder was attacked the patient's control over it became good in 75 per cent., but in diffuse tuberculosis of the bladder control became good in 31·5 per cent. only. Even when the urine had become normal troubles of micturition might continue either from a shrinking of the organ after the tuberculous portion had healed up or from psychical causes. The other kidney when healthy at the time of the operation did not become tuberculous afterwards. In cases where tuberculosis developed afterwards in the other kidney latent germs of the disease had been present already. The other kidney was no less resistant than before, as was proved by the fact that two cases of Bright's disease happening in the remaining kidney ran an exceptionally easy course. Among the patients treated by Professor Israel there were eight who became pregnant and had 15 normal deliveries and two abortions, without any complication attributable to the kidney. Of the ten deaths which were not caused by the operation itself one was due to cancer of the rectum, five to tuberculosis of different organs, three to non-tuberculous affections of the uro-genital system, and one to some unknown cause. The deaths from tuberculosis included three from acute miliary tuberculosis, one from tuberculous meningitis, and one from tuberculosis of the remaining kidney. The non-tuberculous affections included one case of amyloid degeneration of the abdominal organs, one of chronic septicæmia, and one of ascending pyelonephritis. Death occurred in five cases after three months, in one after eight months, in one after 13 months, and in one after eight years. In 62 per cent. of the deaths the patients succumbed to secondary affections which were present at the time of the operation. These patients would possibly have been saved by a more early operation. From the fact that the results were the better the sooner the operation was performed, Professor Israel inferred that spontaneous recovery was almost impossible and that until an internal remedy against tuberculosis of the kidney was discovered nephrectomy should be performed as soon as a tuberculous affection of one kidney was ascertained.

June 3rd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

A Nobly Earned Jubilee.

ON May 26th, in Milan, in the great hall of the "Federazione delle Società Scientifiche," before a numerous assembly of medical men, nature-students, and members of liberal callings, including many distinguished citizens and ladies, was celebrated the fiftieth anniversary of the medical graduation of the Senator Dr. Malachia De Cristoforis. Letters of sympathy were read from men of light and leading all over Italy, after which Dr. Carlo Forlanini, professor of clinical medicine in the University of Pavia, opened the business of the day with an address in the name of the "Associazione Sanitaria" to the Senator De Cristoforis as a man illustrious in science and exemplary in citizenship. This was followed by a speech from the assessor Signor Menozzi conveying the thanks of the city of Milan to the "hygienist and sociologist" conspicuous for his philanthropy and his patriotism. After him came the "oraison de circonstance" of Dr. Luigi Veratti who evoked rounds of applause by an eloquent review of the duty-doing, self-denying life of the hero of the day—a life devoted to the welfare of the community from the humblest to the highest, a life which had been "coincident and co-efficient" with the elimination of the ailments of the artisan and of the "accidents" besetting labour, as well as with notable success in the crusade against tuberculosis and alcoholism. A magnificent album, artistically illuminated and framed, containing the autographs of a long list of admirers among the citizens and professional men of Milan was thereafter presented to the Senator Dr. Malachia De Cristoforis, who made a brief, a touching, and a singularly effective acknowledgment of the honour conferred upon him. "With the people I have shared grief and joy. At the people's side I will be so long as I live." These were his closing words, after which he asked permission to read the following: "Honourable Senator, risen again to new and long life, thanks to your great skill and kindness, I associate myself, from the depth of my heart, with the tokens of affection and esteem of your admirers, and I beg you to receive the expression of my undying gratitude. Your very humble servant, Teresa Parravicini (widow and laundress), your patient at the Ospedale Maggiore in 1872, who still enjoys excellent health." And with this dramatic episode the proceedings came to an end.

A Town of 1700 Inhabitants without a Medical Man!

Sardinia divides with Sicily the claim to be the "Cinderella of Italy," and yet either of them might be made the Island of Prospero. But misgovernment and maladministration haunt them like a twin Caliban, so that from being the *cella penaria* (the granary) of ancient Rome they can hardly keep their own inhabitants from starvation. Just listen to what I learn from Sassari, the northern capital of Sardinia and seat of a university. The population of Santa Maria d'Arzaghena, in consequence of the death of several "puerpere" for want of medical aid, has risen in something like rebellion against the authorities which had promised it the "medico condotto" (divisional practitioner) to which it was entitled. Months have passed and yet the township in question, with its 1700 inhabitants maintaining a life-and-death struggle against poverty and malaria, is still without a medical man. On May 31st, braving every obstacle presented by roads that are little better than bridle-paths, the chief men of the township, after 19 hours' march, waited on the prefect of Sassari, and in words of simple, touching eloquence appealed to him to do something in face of the mortality which has now reached an appalling percentage, and which, unless brought under by effective measures, will rouse the population to deeds of violence. What the prefect's response has been I have yet to learn, but such cases as that of Santa Maria d'Arzaghena are common enough to make Italians inquire, somewhat sadly, whether the "new order" is really an improvement on the "old" or whether Italy can, with peace to her own conscience, pose as a "Great Power" with so much domestic misery unrelieved.

Tuberculosis in the Etiology of Nervous and Mental Ailments.

The Genoese school is honourably identified with medical psychology and prominent among the cultivators of that field is Dr. Morselli, professor of clinical psychiatry in the University. A worthy inheritor of the name, himself an assistant in the medico-psychological clinique, Dr. A. Morselli, has issued a careful and eminently instructive volume under the title "La Tubercolosi nella Etiologia e nella Patogenesi delle Malattie Nervose e Mentali." As throwing fresh and clear light on a theme still obscure but fraught with interest to pathologist and practitioner alike, Dr. Morselli's treatise (Torino: Unione Tipografico-Editrice, 1 vol., 1907) is to be recommended as worthy of translation into English and thereby of a yet larger public than that to which it primarily appeals.

Professor Maragliano's Jubilee.

As I write, a correspondent informs me of another incident connected with the Genoese school—the celebration of the "professorial jubilee" of Dr. Edoardo Maragliano who holds the chair of clinical medicine. Dr. Maragliano has long been an indefatigable worker in the field of tuberculosis, and, associated with his name, a yearly prize will be instituted for the best contribution to the etiology, pathology, and treatment of tuberculous disease. King Victor

Emanuel III. contributes 1000 francs (£40) to the fund required for it. The jubilee, I may add, will be celebrated on June 22nd.

June 1st.

COPENHAGEN.

(FROM OUR SPECIAL CORRESPONDENT.)

The Bacteriology of Antarctic Soil.

Dr. E. Ekelöf has published his investigations into the number of bacteria present in the soil of the Antarctic region made during the stay at Snow Hill of the Swedish Antarctic Expedition in 1901–04. He found a relatively abundant bacterial flora but only in the uppermost five or ten centimetres of the soil. During the cold "winter months," February to November, the number of bacteria in this stratum was on an average 7000 per cubic centimetre. But during the two less cold "summer months," December and January, the number rapidly increased and reached its maximum in January, when it became ten times as high as it was during the coldest months. A peculiarity of the Antarctic bacteria was their very slow growth on culture media, often more than a week being needed to make them appear as macroscopically visible colonies. Another interesting fact about them was that none of them were able to liquefy gelatin and that none of the common bacteria of putrefaction were found. As a result of this it proved possible to keep the flesh of fowl and seal hanging in the open air the whole year round, even during the summer months with their strong sunshine, without the least sign of deterioration of the meat appearing. Dr. Ekelöf is not prepared to state whether pathogenic bacteria are present in the soil of the Antarctic region, but he found none and he thinks that the following circumstance is opposed to the likelihood of their presence. During the two years' sojourn of the expedition at Snow Hill not one of the members suffered from any of the common diseases arising from cold (catarrh, angina, bronchitis, laryngitis, pneumonia, pleurisy, and articular rheumatism). But as soon as they came into the mild climate of South America on their way back these diseases began to occur amongst them.

A Medico-legal Problem in Syphilology.

About one year ago the Danish legislative body carried a law regulating prostitution in Denmark. Before that time a control was established with obligatory medical examination of the *puellæ publicæ*. The new law provides that prostitution is not punishable as such, but the police are authorised to punish as vagabonds females who cannot convince the authorities of their being able to earn their livelihood in a decent manner. The law provides further that all persons, rich or poor, suffering from venereal diseases have a *right* to be cured *gratis* by certain practitioners who in Copenhagen were to be appointed *ad hoc* and paid by the municipality. This regulation, excellent as it is in itself, has had some disagreeable consequences to the profession. At the date at which the law came into force the best-trained specialists abstained from applying for the appointments because they would not run the risk of holding them in company with other not specially trained colleagues, for fear that the public should regard this as a sort of official recognition of the said colleagues as specialists. Only general practitioners were therefore appointed, but during the last six months the public has profited by its right to free treatment to such an extent that the actual specialists have hardly seen any venereal patients. The attention of the Copenhagen Medical Association has been drawn to this abnormal situation, and it is hoped that the association will succeed in inducing the authorities to arrange the important affair in a more reasonable way. It is of the greatest importance that this first instance of a sort of monopolising by the State of certain branches of practice should not be carried out in such a manner as to imply a pecuniary loss to the profession. Should such a thing happen it might prove a very serious precedent, as rumours are afloat that the Government is planning the substitution of a restricted number of physicians appointed and paid by the State in the place of the many hitherto privately practising sick-club doctors. As the sick-clubs, friendly societies, &c., comprise the majority of the population of Denmark, and as the State would, of course, pay as little as possible, it is well that the profession should be fully aware of the possible danger.

May 27th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Coroner's Jury Censures Physicians.

THE recent death of a woman who was under the care of two "Christian Science" healers in this city, but who was not seen by a legally qualified physician capable of giving a certificate of death, led to a coroner's inquest. The result of the inquiry was the exposure of the practice of some medical men of giving certificates of death in cases where the deceased had been attended exclusively by so-called "Christian Science" healers. The jury, many of whom were physicians, returned among other items of their verdict the following: "We find that a number of medical doctors in New York City make it a practice to furnish death certificates for persons who die under so called Christian Science treatment, thus enabling Christian Science practitioners to evade the laws of the State of New York in their so called treatment, and we respectfully call the attention of the Department of Health of New York City and the District Attorney of New York County, and the Medical Society of New York County to the practice of such physicians and request them to take all necessary steps required by law to put a stop to such practice and punish the perpetrators thereof."

International Congress on Tuberculosis.

The National Association for the Study of and Prevention of Tuberculosis has fixed upon the last ten days of September and the first ten days of October, 1908, for the meeting of the Congress on Tuberculosis to be held at Washington. This time is most fitting to foreign delegates. The attendance promises to be very large and every effort will be made to secure success for the work of the Congress. A tuberculosis exhibition will be created which will surpass any similar exhibition in this country. The various departments of the Government have become interested and will coöperate with the association. The latter will provide a fund of $100,000 with which to finance the Congress. Meantime, the American Anti-Tuberculosis League will hold its annual meeting at Atlantic City from June 1st to 4th, 1907, at the same time as the meeting of the American Medical Association. The two subjects for special discussion will be "Tuberculosis in the Negro Race" and "Tuberculosis and Milk."

Health in the Canal Zone.

The improved health in the Canal zone under the strict administration of sanitary regulations, prepared and enforced by a military *régime*, is attracting wide attention. No person could have been more thoroughly qualified for the position of chief sanitary officer, both by education and experience, than Colonel Gorgas of the United States Army. He had been very prominent in establishing and enforcing sanitary regulations in Cuba by which yellow fever had been exterminated in that island where it seemed to be indigenous. The results of his work in the Panama district have been well-nigh marvellous, as the following recent reports show. Since August last the number of sick among the employees has steadily decreased until now it is 19·40 per 1000, as against 33·72 in August. Among the 4600 white employees there were only two deaths from disease during the month of March, equivalent to an annual rate of 5·17 per 1000. Among the 1200 American women and children living in Canal Commission quarters there was not a single death and little sickness existed.

Places maintained by Abortionists are Public Nuisances.

An abortionist recently attempted to escape conviction of the charge of maintaining a public nuisance on the ground that there was no adjudicated case in which it has been held that the maintaining of a house for the purpose of practising the vocation of an abortionist constitutes a nuisance. The Appellate Court of New York, however, held that at common law it would have been, and under the provisions it is, a nuisance for a person by public advertisement to invite and receive a class of the public to his premises for the purpose of violating the laws of the State, as was done in this case; this constitutes "crime against the order and economy of the State by offending public decency."

Commitment of Suspected Insane.

One of the first-fruits of the notorious trial of Thaw is the introduction into the Legislature of a Bill which makes provision for the commitment of a person charged with felony to a State hospital for the insane for the purpose of inquiry as to his sanity. The commitment may be made on the request of either his attorneys or the prosecuting attorneys, and for a term of not less than three nor more than six weeks. It is alleged, in opposition to the measure, that the time is too limited and that an asylum for the insane should not be selected. In regard to time, it is stated that in many cases an insane person might conceal for that length of time his peculiar delusion, illusion, or hallucination, or, on the other hand, a person might successfully feign a form of insanity for this period. The asylum for the insane is objectionable, for if certified as not insane the odium of the commitment to such an institution would ever after cling to him. The Bill is generally heartily approved as an improvement on the present court procedure as illustrated in the Thaw case.

Inspection of Medical Schools.

The council of the American Medical Association has recently instituted an inspection of the medical schools of the United States for the purpose of determining the exact character of their work and to classify them on a civil service basis. The council reports that there are 160 medical schools in the country, which is nearly the number in Great Britain, Germany, France, and Austria combined. They were found to represent every grade, from the very highest, as high probably as those of any country in the world, to the very lowest, a number being little better than diploma mills. The council states that some schools are absolutely worthless, being without equipment for laboratory teaching, without dispensary or hospital facilities. Some were no better equipped for teaching medicine than a Turkish-bath establishment or a barber's shop affords. Many of them are little more than quiz classes, in which men are drilled to enable them to pass examining boards of the States. The council concludes that it is in the power of the State examining boards and the organised profession to place American medicine on an acceptable basis by requiring a higher grade of educational qualification of those entering the schools. These State boards should agree upon a standard of what shall constitute a medical college in good standing and enforce that standard in their examinations of applicants.

Medicinal Foods.

The Council on Pharmacy and Chemistry of the American Medical Association has been investigating the nutritive value of so-called "medicinal foods." The results of this inquiry are as important to the profession as are the investigations, by the same body, of the composition and medicinal value of the various proprietary drugs supplied by manufacturing firms. It is demonstrated that large numbers of the most popular of these foods for the sick have little or no food value. Alcohol is in many instances the most potent factor in liquid preparations. In others the ingredients advertised are either wanting or are worthless as food.

American Association for the Promotion of the Hygiene of Schools.

At a recent conference held in Washington it was decided to organise a National Association for the Promotion of the Hygiene of Schools. The object of the association is to secure the coöperation of all workers in charity and teachers in the public schools in the improvement of the hygienic condition of the schools of the several States. It is believed to be impossible for the schools to take full advantage of their opportunities for the children's welfare without the knowledge of the work of the dispensaries, relief and fresh air agencies, and other forms of promoting the health of this class by workers in charity. It is also deemed of great importance that the latter, in order to do their work intelligently and satisfactorily, should be brought into close connexion with schools and the health authorities. The association will be represented in the Conference on School Hygiene which will assemble in London in August.

May 25th.

DONATIONS AND BEQUESTS.—The treasurer of the Brompton Hospital for Consumption has received £100 from "A. B.," Putney, and a donation of £500 from the trustees of Smith's (Kensington Estate) Charity; the Royal London Ophthalmic Hospital and Charing Cross Hospital have received donations of £500 each from the trustees of Smith's Charity; and the treasurer of the London Fever Hospital has also received a donation of £300 from the trustees of Smith's Charity.

Obituary.

ALFRED SQUARE COOKE, M.R.C.S. ENG., L.S.A.

Mr. Alfred Square Cooke died at his residence, Badbrook House, Stroud, on June 1st, in his sixty-fifth year. He received his medical education at St. Bartholomew's Hospital, becoming qualified as L.S.A. and M.R.C.S. Eng. in 1863 and 1864 respectively. In 1865 he was appointed house surgeon to the old Stroud Hospital. For two years he resided at the hospital, but subsequently he removed from the institution and commenced private practice, though he continued to act as house surgeon for another nine years. It was mainly through the efforts of Mr. Cooke that the present well-equipped and commodious hospital was opened in 1875. The same year he was elected honorary surgeon to the institution, which post he resigned in January, 1906, when he was appointed honorary consulting surgeon. In September, 1906, he was presented with a silver salver and a cheque for 120 guineas from the residents of Stroud and the district, in grateful recognition of 40 years' devoted service to the hospital. Mr. Cooke was a former president of the Gloucestershire branch of the British Medical Association. He at one time had a very extensive practice. He was for 37 years medical officer to the Stroud union workhouse and was also surgeon to the Post-Office and Admiralty. Mr. Cooke will be much missed in Stroud, where he was highly esteemed, and great sympathy is felt there with his widow and seven children.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in May the following candidates satisfied the examiners:—

M.B., B.S. EXAMINATION.

Honours.—*Harold Garfield Bennett, St. Thomas's Hospital; ‡Gerald Tyler Burke and ‖Bertram Walter Cherrett, St. Bartholomew's Hospital; §John Henry Farbstein, University College; †John Athelstan Braxton Hicks, Westminster Hospital; §William Henry Miller, Guy's Hospital; *†‡§Henry John Nightingale (University medal) and †Alfred Charles Foster Turner, St. Thomas's Hospital; and *Charles Wilfred Vining, St. Mary's Hospital.

* Distinguished in Medicine. † Distinguished in Pathology.

‡ Distinguished in Forensic Medicine and Hygiene.

§ Distinguished in Surgery.

‖ Distinguished in Midwifery and Diseases of Women.

Pass.—Godfrey Frederick Ely Allison, Guy's Hospital; Charles James Armstrong-Dash, St. Bartholomew's Hospital; John Stanley Avery, University College, Bristol; Alfred Ball, University College; Alec Barber and Tom Bates, St. Bartholomew's Hospital; Ella Beales, Sylvia Rose Margaret Blackstone, and Mary Alice Blair, London (Royal Free Hospital) School of Medicine for Women; John Frederick Broughton, University College; Stanley William Randolph Colyer, Charing Cross Hospital; Eustace James Carey Dicks, St. Mary's Hospital; Kenelm Hutchinson Digby, Guy's Hospital; Allan Baines Fearnley and John Ferguson, St. Bartholomew's Hospital; Kenneth Mayoh Gibbins, St. Mary's Hospital; Elliott Thornton Glenny, St. Bartholomew's Hospital; Samuel Lewis Graham, University College; Arthur Donald Griffith, King's College; Leopoldine W. D. Griffiths, London (Royal Free Hospital) School of Medicine for Women; Sidney Wilfred Grimwade, St. Thomas's Hospital; George Hamilton, Guy's Hospital; Horace Bryden Hill, St. Bartholomew's Hospital; Frank Norman S. Hitchcock, St. Thomas's Hospital; Frank Percival Hughes, Guy's Hospital; Gwilym Gregory James, Westminster Hospital; Sidney Herbert James Kilroe, Victoria University; Herbert Stanley Knight, Guy's Hospital; Janet E. Lane-Claypon, D.Sc., London (Royal Free Hospital) School of Medicine for Women; Alexander Manuel, St. George's Hospital; Marian Mayfield and Emily Helen Morris, London (Royal Free Hospital) School of Medicine for Women; Frederic Miller Neild, St. Thomas's Hospital; Geoffrey Eugene Oates, St. Mary's Hospital; Catherine Payne, London (Royal Free Hospital) School of Medicine for Women; August Frederick Perl and Arthur John Scott Pinchin, St. Thomas's Hospital; John Mackay Plews, St. Bartholomew's Hospital; David Ranken, University of Durham; Frank Douglas Roberts, London Hospital; Cecil Frederick Robertson, Middlesex Hospital; Francis William Schofield, Victoria University; Henry Joste Smith, Guy's Hospital; Ronald Ernest Todd, St. Thomas's Hospital; James Aubrey Torrens, St. George's Hospital; Stuart William Jackson Twigg, University College; Joseph Unsworth, University of Liverpool; Thomas William Wade, Charing Cross Hospital; Norman Hamilton Walker, St. Bartholomew's Hospital; Thomas Edgar Walker, University of Liverpool; Robert James Waugh, St. Bartholomew's Hospital; David Wilson, St. Thomas's Hospital; Alfred William George Woolforde, St. Bartholomew's Hospital; and Carl Ernst Zundel, London Hospital.

The following candidates have passed in one of the two groups of subjects:—

Group I.—Leonard Christopher Blackstone, University College; Emily Susan Cooke, London (Royal Free Hospital) School of

Medicine for Women; Reginald Lionel E. Downer, St. Bartholomew's Hospital; Thomas Scarbrough Dudding, London Hospital; Edward Henry Hugo, Charing Cross Hospital; Mary O'Brien, London (Royal Free Hospital) School of Medicine for Women; Evelyn Henry Bardens Oram, St. George's Hospital; Edgar Nelson Ramsbottom, Victoria University and University of Durham; and Harry Gordon Webb, St. George's Hospital.

Group II.—Laurence Ball, University of Birmingham; Walter Rowley Bristow, St. Thomas's Hospital; Thomas Edmund Ashdown Carr, Guy's Hospital; Herbert Stanley Chate, B Sc., St. Mary's Hospital; David Morgan Davies, Charing Cross Hospital; Carel C. Alexander De Villiers, Guy's Hospital; Hendrik Houwink, London Hospital; Douglas Walter Hume, St. Bartholomew's Hospital; Alfred John Lee, University College; George William Lloyd, St. Bartholomew's Hospital; Clement Lovell, University College; John Clarke Mead, St. Bartholomew's Hospital; Emily Mary Spencer Mecredy, London (Royal Free Hospital) School of Medicine for Women; Edgar Lionel Robert Norton, Guy's Hospital; John Paulley, St. Bartholomew's Hospital; John George Phillips, University College and Guy's Hospital; Edward Selby Phipson, University of Birmingham; Russell John Reynolds, Guy's Hospital; Marie Simpson, London (Royal Free Hospital) School of Medicine for Women; Frank Standish, London Hospital; Robert Yelverton Stones, London Hospital; and Reginald Stephen Townsend, St. Bartholomew's Hospital.

B.S. EXAMINATION.

Pass.—John Acomb, University of Leeds; Dora Elizabeth Lidgett Bunting, London (Royal Free Hospital) School of Medicine for Women; Edward Cecil Brearey Ibotson, Guy's Hospital; Rees Phillips, Middlesex Hospital; Frank Tratman, M.D., London Hospital; and Hilda Kate Whittingham, London (Royal Free Hospital) School of Medicine for Women.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

UNIVERSITY OF CAMBRIDGE.—A grant of £150 has been made from the Balfour Fund to Mr. W. E. Agar of King's College in furtherance of his zoological expedition to the Paraguayan Chaco.—The degree of LL.D. *honoris causâ* is to be conferred on the King of Siam at a special congregation to be held by His Grace the Chancellor at Devonshire House on June 25th.—At a congregation on May 23rd the following degrees were conferred:—

M.B. and B.C.—H. F. G. Noyes, Caius.

M.B.—C. R. Crowther, St. John's; J. R. C. Greenlees, St. John's; and G. F. S. Bailey, Caius.

B.C.—A. I. Cooke, Caius; and R. F. Young, Christ's.

—The Rev. E. S. Roberts, Master of Gonville and Caius College, has been re-elected vice-chancellor for the ensuing academical year; Sir Isambard Owen, has been reappointed a governor of the University College of Wales, Aberystwyth; Mr. F. A. Potts, Trinity Hall, has keen appointed assistant superintent of the Museum of Zoology; and Mr. Keith Lucas, Trinity, has been appointed an additional demonstrator in physiology.—Courses of lectures in pharmacology, pathology, protozoology, surgery, midwifery, medicine, and hygiene will be given at the Medical School during the Long Vacation. Syllabuses and time-tables are published in the *University Reporter* of June 4th. It is proposed to institute a paper in Heat and Chemistry as an alternative to "Paley's Evidences" or Logic in the previous examination.—The Vice-Chancellor has been authorised to accept a tender for the extension of the Cavendish Laboratory of Physics at a cost of £7135. A similar extension of the chemical laboratory, at a cost of £13,500, is to be proceeded with during the summer.—Professor Bradbury, Dr. G. N. Pitt, Professor W. Osler, and Dr. Rose Bradford have been appointed examiners in medicine; Dr. W. Rivers Pollock and Professor H. R. Spencer, examiners in midwifery; and Mr. T. H. Kellock, Professor H. G. Barling, Mr. Stanley Boyd, and Mr. L. A. Dunn, examiners in surgery for the ensuing academical year.—A complimentary banquet was given to Principal Donald MacAlister on June 4th in the combination room of St. John's College.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual meeting of the College was held on June 1st, when a very favourable report was submitted to the Fellows. During the year 17 candidates, having passed the examinations, were admitted to the Fellowship; 73 candidates, having passed the conjoint examination with the Royal College of Physicians of Ireland, received the diploma in surgery and midwifery; 29 candidates, having passed the conjoint examination with the Royal College of Physicians, received the conjoint diploma in public health; ten candidates, having passed the examinations, received the licence in dental surgery; and 64 candidates, having passed the conjoint preliminary examination with the Royal College of Physicians, received certificates. The obituary list showed the death of six Fellows, 51 Licentiates, and three Licentiates in Dental Surgery. There are at present living 15 Honorary Fellows, 466 Ordinary Fellows, 2908 Licentiates, six Honorary Diplomates in Public Health, 269 Ordinary Diplomates in Public Health, and 531 Licentiates in Dental Surgery.—A meeting of the College was held on June 3rd when the following were elected: President: Mr. Henry R. Swanzy. Vice-President: Mr. John Lentaigne. Council: Mr. William Stoker, Sir Charles A. Cameron, Mr. John B. Story, Sir Charles B. Ball, Sir Thomas Myles, Sir Arthur Chance, Dr. Richard D. Purefoy, Sir Lambert H. Ormsby, Mr. Henry G. Sherlock, Dr. R. Bolton McCausland, Mr. John S. M'Ardle, Mr. Robert H. Woods, Dr. R. Lane Joynt, Dr. Thomas Donnelly, Mr. William Taylor, Dr. Edward H. Taylor, Mr. R. Charles B. Maunsell, Dr. William Ireland de C. Wheeler, and Mr. D. Edgar Flinn.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—The annual meeting and dinner of this association took place on May 31st. The former was held at the rooms of the Medical Society of London at 4 P.M., when the new scheme for the reconstitution of the University, as announced in the Draft Act, was discussed at considerable length and a motion unanimously carried in favour of the measure, subject to certain modifications in details on the lines suggested by the Northern and Southern councils of the association. The annual dinner, held at the Imperial Restaurant, Regent-street, London, W., took place in the evening at 7.30. The newly elected president, Dr. Charles W. Chapman, occupied the chair, supported by 63 members and guests. Excellent music was provided under the direction of Miss Jessica Leeson and contributed in no small degree to the success of the gathering.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on May 30th, Dr. F. H. Champneys being in the chair. A letter was received from the Privy Council transmitting an Order in Council approving the revised rules for the period ending Sept. 30th, 1909. A letter was considered from the Privy Council transmitting a copy of a letter from the medical officer of health of the city of Manchester with regard to a proposed additional rule that midwives should be compelled to take the temperature of patients at every visit. The Board decided that the Privy Council should be informed that the proposal will receive the careful consideration of the Board on the next revision of the rules. A letter was read from Mr. Framjee Gotla inquiring whether a teacher who has instructed a pupil by correspondence only is entitled to sign the certificate of instruction on the pupil's behalf. The Board decided that Mr. Gotla be informed that the terms of the certificate of instruction, and in particular the words "attended" and "lectures," appear to preclude the possibility of the signature of the certificate by a teacher whose three months' course of instruction has been given wholly or partly by correspondence. The following item in the report of the Midwives Act amendment committee was not reached before the adjournment of the Board: the committee recommends the Board to resolve that it is desirable to amend the Act so as to provide, among others, for the following alteration:—

> Local supervising authorities and boards of guardians to be enabled to pay reasonable fees to medical practitioners sent for in emergencies in accordance with the rules of the Board, with power to recover the fee from the patient or her husband in suitable cases.

INTERNATIONAL NURSING CONFERENCE.—An International Nursing Conference will be held in Paris on June 18th, 19th, and 20th under the auspices of the International Council of Nurses. The General Director of the Assistance Publique, M. Mesureur, will act as president of the first session of the Conference and will give an address on the Work of the Assistance Publique for Nursing Education. He will be supported by Dr. Bourneville, Madame Alphen Salvador (who has established a training school for nurses in Paris on modern lines), Dr. Lande (administrator of civil hospitals in Bordeaux), and Dr. Anna Hamilton. Other sessions of the Conference will deal with the Practical Training of Nurses; the Public and Social Responsibilities of the Nurse; Professional Organisation; International Nursing Reciprocity, when a discussion on the opportunities for nurses in a foreign land will be opened by Miss C. Elston, an English trained nurse, now *directrice* of the Civil Hospital and Training School for Nurses at Tondu, Bordeaux; and the History of the Professional Nursing Press, when representatives of the German, Dutch, Danish, French, American, British, Canadian, and Australian nursing papers will take part in a debate. The members of the Conference will be received by the Municipal Council of Paris at the *Hôtel de Ville*, by the

Assistance Publique at the New Nursing College at the Salpêtrière Hospital, and at Chantilly by the Baroness James de Rothschild, while other invitations to visit hospitals and kindred institutions have been received.

Longevity.—Mrs. Mary Davies of Ystradmynach attained the 103rd anniversary of her birthday on May 24th.

Medical Barristers.—The following names appear in the list of those who are to be "called" during Trinity Term, 1907:—By the Middle Temple: Mr. M. I. Fincane, M.R.C.S. Eng., L.R.C.P. Lond. By Lincoln's Inn: Mr. Meredith Young, M.D., M.S. Edin., D.P.H., of Stockport; and Mr. T. W. N. Barlow, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. By the Inner Temple: Mr. A. R. Henry, of Guy's Hospital. Amongst those listed for call to the bar at the King's Inns, Dublin, to-day (Saturday, June 8th) is Mr. J. C. McWalter, M.D. Brux., F.F.P.S. Glasg.

Hampstead Garden Suburb: a Novel Foundation Stone-laying.—The committee of the Hampstead Tenants' Society has lost no time in getting to work The first sod of the new building adventure was only cut by Mrs. S. A. Barnett on May 2nd, but the committee was able to invite each of the first 100 members of the society to lay a foundation-stone on Wednesday, June 5th. In connexion with the ceremony Mrs. Henry Jephson, the first member of the society, invited all the members to tea in the tea-gardens of the "Royal Oak" Hotel, Finchley-road. The Bath Stone Firms, Limited, gave the society 100 foundation-stones, each bearing the initials of a member, while a silver-plated trowel was handed to each member, with his or her initials and number in the society engraved on it, with which to perform a percentage of the ceremony, whose collective form was designed by the committee to demonstrate that the houses on their part of the estate are owned collectively. Mr. Henry Vivian, M.P., presided over the stone-laying ceremony, which was, unfortunately, performed for the most part in drenching rain.

The Glasgow University Club Dinner.—The Glasgow University Club celebrated its twenty-first year of existence by a highly successful dinner at the Trocadéro Restaurant, London, W., on May 31st. Principal Donald MacAlister, in academic costume, occupied the chair and on his right hand was the Right Hon. Lord Kelvin, O.M., G.C.V.O., President of the club for this year. The principal guest was Sir Lauder Brunton. There was a large and distinguished gathering which included Sir Henry Craik, Sir John Batty Tuke, M.P., Sir Thomas McCall Anderson, Sir John Tweedy, Professor J. M. Thomson, Professor John Ferguson, Professor A. H. Young, Professor R. Latta, Professor William Jack, Professor W. P. Ker, Professor J. Harvard Biles, Professor W. S. McCormick, Professor D. W. Finlay, and Professor Blacklock Henderson, the Rev. David McEwen, D.D., Dr. George A. Heron, Dr. D. C. McVail, Dr. C. O. Hawthorne, Dr. Craig Henderson, Dr. Guthrie Rankin, Dr. R. Bishop, Dr. James McClure, Mr. J. W. T. MacAlister, and many others, the majority of whom were medical men. Principal MacAlister, in giving the toast of "The University and Club," referred to his unexpected translation from Cambridge on the lamented death of Principal Story. After enumerating some of the many distinguished sons of the University of Glasgow who have made a name for themselves in England and abroad in many spheres of work he made an appeal on behalf of the Students' Union at Glasgow, which was the sole expression of the University's solicitude for her students outside the class-rooms. An extension of its buildings was urgently needed and he appealed to all members of the club to help the students to raise the necessary £2500. If all who had succeeded in life through bursaries held at Glasgow would repay a part of their obligation another 2000 students might be provided for. Lord Kelvin, president of the club, on rising to reply, received an ovation. In a very vigorous and genial speech he said that from his earliest associations he could claim to be a true child of the University. He strongly advocated the acquisition of Latin and Greek as the first foundations of education and he rejoiced that the Scotch universities still insisted on the "inoculation" of all their students with at least small doses of logic and metaphysics before they took up the studies of their special faculties, and he humorously showed the advantages that they derived from the consequent "immunity" against philosophic errors in after-life. He insisted that the function of a university was to teach its students knowledge other than that for which they had a natural taste. Sir William Ramsay proposed "The Guests," on whose behalf Sir Lauder Brunton and Dr. George Ogilvie replied, and The Chairman's Health was given by Dr. Heron. During the evening a telegram was sent to Lord Lister cordially expressing the affectionate regard in which the club held him and assuring him of its gratitude for the interest which he had always shown in the club, of which he is an original member. The club forms an important link between the University of Glasgow and its graduates in England. Its prosperity is proved by a satisfactory balance-sheet for the last year.

Golden Wedding Celebration.—Mr. and Mrs Samuel Stretton of Hampton House, Droitwich, celebrated their golden wedding recently at the Town Hall, Kidderminster. Among the many presents received were a large rose bowl from the subscribers to the Infirmary and Children's Hospital, a golden cup from their children (of whom there are 12), and a chased golden cream jug and sugar castor, the gift of the Mayor and Mayoress. Mr. and Mrs. Samuel Stretton went to Kidderminster soon after their marriage and removed to Droitwich a few years ago. They have always taken great interest in the welfare of the Kidderminster Infirmary, and the sick and suffering poor of the town and neighbourhood possess in them true friends. Soon after qualifying as M.R.C.S. Eng. in 1854 Mr. Stretton saw service as a volunteer in the Crimean war, and on his return home he soon acquired a large general practice. He is senior consultant surgeon of the Kidderminster Infirmary (at which institution one of his sons, Mr. Lionel Stretton, is the present senior surgeon) and a justice of the peace for the county of Worcester.

Medical Golf Tournament.—The Medical Golfing Society held a tournament on May 30th at Burnham Beeches Golf Club, the links of which club had been kindly placed at the disposal of the society. The challenge cup presented by Mr. Henry Morris for the best score against Bogey under handicap was won by Dr. F. J. Smith, who was "all square" with Bogey. Dr. Smith also secured the gold medal presented by the Medical Golfing Society to the winner of the cup, and he further carried off the first prize in Class II. for players with handicaps over 12, the second prize being gained by Dr. Seymour Taylor with a score of 1 down to Bogey. The prize offered for the best last 9 holes v. Bogey in Class II. was awarded to Dr. H. Lambert Lack with a score of 1 up. Class I. for players with handicaps of 12 and under attracted a numerous entry and resulted in Dr. R. J. Probyn-Williams, Dr. E. F. Buzzard, and Dr. C. M. Anderson, handing in scores of 1 down to Bogey. The best score v. Bogey for the last nine holes in Class I. was won by Mr. Harold A. Kidd who was 1 up. The foursome sweepstake was won by Mr. T. H. P. Kolesar and Mr. W. Rushton with 2 up on Bogey, the second place being tied for with all square by Mr. G. C. Bell and Mr. T. M. Young, Mr. H. M. Rigby and Mr. F. B. Cooper, and Dr. C. M. Anderson and Mr. J. R. Walker.

Medico-Legal Society.—Mr. Justice Walton presided over the first banquet of the Medico-Legal Society held on June 4th at the Holborn Restaurant, London, W.C. Sir W. J. Collins, M.P., in proposing the "Bench and Bar," suggested the advisability of founding a school of forensic medicine for the more precise study of medical jurisprudence. The toast was responded to by Lord Justice Kennedy who, in discussing the question of sentences for crimes in relation to lunacy and uncontrolled impulses, pointed out that the truest humanity did not always exist in unlimited mercy, and by Mr. W. English Harrison, K.C., who said that the common object in life for doctors and barristers was the elucidation of truth. "The Medical Profession" was submitted by Sir E. Clarke, K.C., who contrasted the comfortable conditions in which lawyers worked and the unfavourable circumstances that attended the labours of doctors in many instances; he expressed surprise that the medical profession had so many recruits and concluded that young men joined it because of their inclination to occupy their lives in doing good. The toast was acknowledged by Sir R. Douglas Powell, who showed how closely the two professions of law and medicine came into contact, especially in lunacy and insurance work, and by Mr. Henry Morris, who described the efforts now being made to prevent unqualified medical practice. Sir Edward R. Henry, in proposing the toast of "The Medico-Legal Society," explained fully the possibilities of the use of finger-prints, not only for police purposes, but for general work. Mr. Justice Walton, in replying, observed that the society could with advantage take up the subject of sanitary legislation. The toast of "Our Guests," given by Dr. F. J. Smith, was responded to by his Honour Judge J. A. Rentoul, and after Mr. Justice Walton had suitably replied to the toast of "The President," submitted by Mr. W. Blake Odgers, K.C., the proceedings terminated with hearty congratulations to the honorary secretary, Mr. R. Henslowe Wellington, on the success of the evening.

NOTES ON CURRENT TOPICS.

The Butter and Margarine Bill.

THE Standing Committee of the House of Commons which has been dealing with the Butter and Margarine Bill decided by 26 votes to 19 not to accept Sir FRANCIS LOWE's amendment imposing a 16 per cent. moisture limit on milk-blended butter. The rejection of the amendment was only secured after Sir EDWARD STRACHEY reiterated the undertaking of the Board of Agriculture that the substance which has hitherto borne that name would no longer be exposed for sale under any title containing the word "butter." By the regulations of the Board it would have to be described so as to make it clear to the intelligence of the ordinary working man and woman that the article they were buying was not butter in any sense of the word.

The Society of Apothecaries of London Bill.

The Society of Apothecaries of London Bill has been read a third time in the House of Commons and passed without amendment.

The Notification of Births Bill.

Several changes have been introduced into the Notification of Births Bill at the instance of the Government during its passage through a Standing Committee of the House of Commons. This measure was introduced by Lord ROBERT CECIL with a view to aid in the efforts being made to combat infantile mortality. It provided for the notification of births within 48 hours of their occurrence. Mr. BURNS, the President of the Local Government Board, when the Standing Committee met on Monday, announced that the Government, after considering the Bill fully, had come to the conclusion that certain alterations ought to be made in its terms. It thought that it should be optional and not compulsory for the local authorities to adopt it within their areas. However, the Local Government Board proposed to reserve powers to put the measure in force in the area of any local authority where it thought that obvious advantage must ensue. The Bill placed the period of notification at 48 hours. The Government proposed that the period should be reduced to 36 hours. Mr. BURNS then moved his amendment making the measure adoptive. Mr. JOHN WARD, Mr. TENNANT, and several other members of the committee protested against this change which they believed would take the strength out of the Bill. Mr. BURNS, however, expressed confidence that the large towns would adopt it. The great benefit of notification, he considered, would be that through the medical officer, ladies, public health visitors, and others would visit the mother, help her with advice, and, if advisable, induce her to give the child natural rather than artificial food. Mr. BURNS's amendment was ultimately carried by 19 votes to 15. Other amendments, including the one reducing the period of notification to 36 hours, were also inserted in the Bill, which passed through committee and was reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, MAY 29TH.

Tuberculosis in Cows.

Mr. WATT asked the Secretary for Scotland whether he would state, for the years 1900 to 1906 inclusive, the number of cows examined by veterinary surgeons under Article 3 of the Dairies, Cowsheds, and Milkshops Order, 1899, the number of cows certified under the said Article to be affected with tuberculosis of the udder, and the manner in which the cows so certified were disposed of.—Mr. SINCLAIR furnished the following written reply: The figures compiled from the returns made to the Local Government Board from 1900 to 1905 are as follows:—

—	Year.					
	1900	1901	1902	1903	1904	1905
Number of cows examined	20,076	22,604	26,392	29,870	29,303	32,309
Number of cows affected with tuberculosis of the udder	54	46	40	40	37	43

These figures, however, are only approximate and do not represent the exact number of cows certified as affected by tuberculosis of the udder, which I am unable to obtain. I have no information as to how the cows certified were disposed of.

Infantile Mortality.

Mr. RIDSDALE asked the President of the Local Government Board to give figures relating to the infant mortality in the boroughs of Battersea, Lambeth, Woolwich, Bradford, Burnley, Ashton-under-Lyne, Liverpool, and St. Helens.—Mr. BURNS replied by furnishing an elaborate table of statistics, from which the following figures are abstracted:—

Name of borough.	Year.	Deaths of infants. Number.	Deaths of infants. Per 1000 births.	Name of borough.	Year.	Deaths of infants. Number.	Deaths of infants. Per 1000 births.
Battersea ...	1904	706	146	Ashton-under-Lyne	1904	207	172
	1905	550	114		1905	212	179
	1906	588	126		1906	183	153
Lambeth ...	1904	1328	147	Dukinfield ...	1904	96	193
	1905	1127	128		1905	91	196
	1906	1086	131		1906	91	176
Woolwich ...	1904	466	132	Liverpool ...	1897	4488	201

Burnley ...	1904	625	233		1905	430	132
	1905	465	174		1906	489	153
	1906	612	215				

THURSDAY, MAY 30TH.

Parish Midwives.

Mr. REMNANT asked the President of the Local Government Board whether he could state the number of midwives who were employed during the last or any recent period of 12 months as parish midwives; whether midwives so employed were regarded as Poor-law officers; and whether any order of the Board had been issued with regard to their appointment.—Mr. BURNS replied (by written answer): I am not in a position to give the information desired by my honourable friend. The midwives referred to would not usually be regarded as Poor-law officers. There is no order of the Local Government Board with regard to their appointment.

Inquest Fees.

Mr. CLAUDE HAY asked the President of the Local Government Board whether he could state the number of inquests held on persons who died in London workhouses and infirmaries during the latest year for which the figures were available; the proportion of inquests held to the total number of deaths in such institutions, and the number of inquests held on persons over 60 years of age, and the proportion to the total number of deaths over that age; whether he could say what was the general practice in regard to the holding of inquests, and what were the fees paid to medical officers and coroners in connexion therewith.—Mr. BURNS furnished a written reply as follows: I have made inquiry but I do not find that any official returns give the particulars desired by the honourable Member. The subject of coroners and inquests is not within my province but I may state that the London coroners are paid fixed salaries and that a medical man who attends an inquest on a summons from the coroner is entitled under the Coroners Act, 1887, to a fee of one guinea for attending to give evidence at an inquest at which he has made no post-mortem examination, and of two guineas for making a post-mortem examination and attending to give evidence thereon.

Public Health in Scotland.

The House was engaged all day in discussing Scottish votes in Committee of Supply. Several matters relating to public health were raised on the vote of £3387 for the services and expenses of the Local Government Board in Scotland.

Mr. WEIR complained of the inadequacy of medical inspection in Scotland. The sanitary conditions which prevailed in the island of Lewis, he said, called for increased vigilance on the part of the Local Government Board.

Mr. WATT made some observations on the irregularities of meat inspection in Scotland. Some localities did not carry out the instructions of the Local Government Board and the districts which did obey the instructions were placed at a disadvantage. He urged that the Board should be more strict in its regulations regarding the importation of chilled beef. It would be beneficial if a skilled veterinary surgeon were appointed to have the supervision of the whole of Scotland in regard to this matter.

Mr. GULLAND congratulated the Secretary for Scotland on the steps taken by the Local Government Board to check consumption. He believed that the excellent circular issued by the Board in March of last year would lead to good results. Deaths from the disease showed a decrease and he hoped the decrease would continue. The circular had asked the local authorities to adopt compulsory notification. Edinburgh was the first city to go in for it. He believed that many other authorities shrank from compulsory notification because they felt that it would expose the people who notified to a sort of boycott. He could assure the right honourable gentleman that the country agreed with [illegible] the Local Government Board for Scotland [illegible] Scotland.

This measure was introduced by Lord ROBERT CECIL with a view to aid in the efforts being made to combat infantile mortality. It provided for the notification of births within 48 hours of their occurrence. Mr. BURNS, the President of the Local Government Board, when the Standing Committee met on Monday, announced that the Government, after considering the Bill fully, had come to the conclusion that certain alterations ought to be made in its terms. It thought that it should be optional and not compulsory for the local authorities to adopt it within their areas. However, the Local Government Board proposed to reserve powers to put the measure in force in the area of any local authority where it thought that obvious advantage must ensue. The Bill placed the period of notification at 48 hours. The Government proposed that the period should be reduced to 36 hours. Mr. BURNS then moved his amendment making the measure adoptive. Mr. JOHN WARD, Mr. TENNANT, and several other members of the committee protested against this change which they believed would take the strength out of the Bill. Mr. BURNS, however, expressed confidence that the large towns would adopt it. The great benefit of notification, he considered, would be that through the medical officer, ladies, public health visitors, and others would visit the mother, help her with advice, and, if advisable, induce her to give the child natural rather than artificial food. Mr. BURNS's amendment was ultimately carried by 19 votes to 15. Other amendments, including the one reducing the period of notification to 36 hours, were also inserted in the Bill, which passed through committee and was reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, MAY 29TH.

Tuberculosis in Cows.

Mr. WATT asked the Secretary for Scotland whether he would state, for the years 1900 to 1906 inclusive, the number of cows examined by veterinary surgeons under Article 3 of the Dairies, Cowsheds, and Milkshops Order, 1899, the number of cows certified under the said Article to be affected with tuberculosis of the udder, and the manner in which the cows so certified were disposed of.—Mr. SINCLAIR furnished the following written reply: The figures compiled from the returns made to the Local Government Board from 1900 to 1905 are as follows:—

—	Year.					
	1900	1901	1902	1903	1904	1905
Number of cows examined	20,076	22,604	26,382	29,870	29,305	39,309
Number of cows affected with tuberculosis of the udder	54	46	40	40	37	43

These figures, however, are only approximate and do not represent the exact number of cows certified as affected by tuberculosis of the udder, which I am unable to obtain. I have no information as to how the cows certified were disposed of.

Infantile Mortality.

Mr. RIDSDALE asked the President of the Local Government Board to give figures relating to the infant mortality in the boroughs of Battersea, Lambeth, Woolwich, Bradford, Burnley, Ashton-under-Lyne, Liverpool, and St. Helens.—Mr. BURNS replied by furnishing an elaborate table of statistics, from which the following figures are abstracted:—

Name of borough.	Year.	Deaths of infants.		Name of borough.	Year.	Deaths of infants.	
		Number.	Per 1000 births.			Number.	Per 1000 births.
Battersea ...	1904	706	146	Ashton-under-Lyne	1904	207	172
	1905	550	114		1905	212	179
	1906	688	126		1906	183	153
Lambeth ...	1904	1328	147	Dukinfield ...	1904	96	183
	1905	1127	128		1905	91	196
	1906	1086	131		1906	91	176
Woolwich ...	1904	466	132	Liverpool ...	1897	4483	201
	1905	364	103		1900	4247	186
	1906	388	109		1904	4780	196
Bradford ...	1904	1048	167		1905	3762	154
	1905	873	144		1906	4145	172
	1906	904	152	St. Helens ...	1904	578	174
Burnley ...	1904	625	233		1905	430	132
	1905	465	174		1906	489	153
	1906	612	215				

THURSDAY, MAY 30TH.

Parish Midwives.

Mr. REMNANT asked the President of the Local Government Board whether he could state the number of midwives who were employed during the last or any recent period of 12 months as parish midwives; whether midwives so employed were regarded as Poor-law officers; and whether any order of the Board had been issued with regard to their appointment.—Mr. BURNS replied (by written answer): I am not in a position to give the information desired by my honourable friend. The midwives referred to would not usually be regarded as Poor-law officers. There is no order of the Local Government Board with regard to their appointment.

Inquest Fees.

Mr CLAUDE HAY asked the President of the Local Government Board whether he could state the number of inquests held on persons who died in London workhouses and infirmaries during the latest year for which the figures were available; the proportion of inquests held to the total number of deaths in such institutions, and the number of inquests held on persons over 60 years of age, and the proportion to the total number of deaths over that age; whether he could say what was the general practice in regard to the holding of inquests, and what were the fees paid to medical officers and coroners in connexion therewith.—Mr. BURNS furnished a written reply as follows: I have made inquiry but I do not find that any official returns give the particulars desired by the honourable Member. The subject of coroners and inquests is not within my province but I may state that the London coroners are paid fixed salaries and that a medical man who attends an inquest on a summons from the coroner is entitled under the Coroners Act, 1887, to a fee of one guinea for attending to give evidence at an inquest at which he has made no post-mortem examination, and of two guineas for making a post-mortem examination and attending to give evidence thereon.

Public Health in Scotland.

The House was engaged all day in discussing Scottish votes in Committee of Supply. Several matters relating to public health were raised on the vote of £3387 for the services and expenses of the Local Government Board in Scotland.

Mr. WEIR complained of the inadequacy of medical inspection in Scotland. The sanitary conditions which prevailed in the Island of Lewis, he said, called for increased vigilance on the part of the Local Government Board.

Mr. WATT made some observations on the irregularities of meat inspection in Scotland. Some localities did not carry out the instructions of the Local Government Board and the districts which did obey the instructions were placed at a disadvantage. He urged that the Board should be more strict in its regulations regarding the importation of chilled beef. It would be beneficial if a skilled veterinary surgeon were appointed to have the supervision of the whole of Scotland in regard to this matter.

Mr. GULLAND congratulated the Secretary for Scotland on the steps taken by the Local Government Board to check consumption. He believed that the excellent circular issued by the Board in March of last year would lead to good results. Deaths from the disease showed a decrease and he hoped the decrease would continue. The circular had asked the local authorities to adopt compulsory notification. Edinburgh was the first city to go in for it. He believed that many other authorities shrank from compulsory notification because they felt that it would expose the people who notified to a sort of boycott. He could assure the right honourable gentleman that the country agreed with of limited companies under the Companies Act, 1862-1900 while the prohibitive conditions of the *Dental Acts* may be entirely avoided. This matter deserves the serious consideration of all who are interested in such business seeing that the contemplated legislation would probably be aimed directly at them, with the view of rendering their present methods illegal For obvious reasons, it is inadvisable for us to go fully into the matter in this letter, but we shall be glad to give you the fullest information on the subject, if you desire it, without charge or to make an appointment for a personal interview here In addition to the benefits to be gained by avoiding the onerous conditions of the Dental Acts, substantial advantages accrue by carrying on business as a limited company from the general *trader's* point of view *These are briefly referred to* in our booklet, 'Limited,' a copy of which we have the pleasure of enclosing, and we would particularly direct your attention to page 7, where an illustration is given of a 'private' or 'one-man' company *We shall be glad to* hear from you upon this subject All communications will be treated as *strictly confidential.*"

Dr Macalister said that he would not give the name of the company as he did not want to advertise it

In answer to Lord Ludlow, Dr Macalister admitted that the *Dental Bill now before the committee* would allow a *number of* qualified men to form a company

Lord Ludlow pointed out that in the case *of Lord Halsbury's* Bill it was proposed that it should be unlawful for a company to carry on the profession of surgeons, *physicians, dentists, or midwives*

The Chairman: Why do the terms of the present Bill differ from the Bill brought forward by Lord Halsbury?

Dr Macalister: The legal advisers of the General Medical Council came to the decision that we should proceed on the lines of the *Bill now* before your lordships. It appeared that in the House of Commons strong representations were made on behalf of certain dental *interests to the* effect that there were perfectly legitimate corporations formed to practise dentistry on the mechanical side of the profession and they would be hampered if this absolute prohibition were insisted on. That was a matter upon which great difference of opinion existed in the dental profession Their counsel had advised them to get rid of the great mischief of treatment by unqualified persons They accordingly put forward the Dental Bill in its present form to get rid of opposition. They asked their lordships for the minimum which touched them most in order to get rid of the maltreatment of the public

Lord Knutsford: Do you approve of the sections now framed in the *Dental Bill?*

Dr Macalister So far as the sections are framed they will prevent maltreatment of the patient by the unskilled person

Lord Ludlow: In your opinion do you approve of there being such a thing as a dentist's *company?* I want your personal opinion.

Dr Macalister I certainly do not approve of it.

Mr. W. Bromfield Paterson, F R C S Eng., L D S, chairman of the Representative Board of the British Dental Association, was the next witness He submitted that the carrying on of dental work by a company did not fulfil any useful purpose other than profit to the company and was detrimental to the public interest. The companies which supplied dentures extracted teeth and did other things for preparing the mouth, but, generally speaking this was done by unqualified persons who made their practice subsidiary to the sale of dentures If that was the main object of their business it was obviously *to their interest* to take out as many teeth as possible, regardless of the patient's real requirements, in order that dentures might be sold. That that was done in the most flagrant manner was well known. In all cases dental companies advertised profusely and generally speaking were unscrupulous in making extravagant professions about the skill of their operators. By means of these statements they attracted people away from qualified men. So far as possible dental companies ought to be prohibited by law. If it was impossible to deal thus with existing companies the formation of dental companies in the future ought strictly to be prohibited. He thought that the Dental Bill before the committee ought to be strengthened in many important respects.

Mr W H. Dolamore, M R C S Eng, L.R.C P Lond., L D S, late honorary secretary to the British Dental Association, *also urged* that the Dental Bill should be made more stringent. He had *come across* many cases of maltreatment of patients by unqualified men. He had objections even to companies formed by qualified men as he feared that the proprietors of a company would in course of time become unregistered men. The best *men* in the dental profession would not form companies.

Mr A. O Curtis-Hayward, solicitor *to* the British Dental *Association, also* gave evidence. He asked that the Dental Bill should be made more strict in its terms so as to check company practice He thought that Bill would be mischievous to the extent that it gave companies any status at all. He would infinitely prefer the clauses in Lord Halsbury's Bill to the present measure

Mr Leonard Matheson, who was President of the British Dental Association last year, was *also* examined. He feared that the Dental Bill in its present form would do more harm than good It would give companies a *certain legal* status. He felt strongly that practice by companies, even *of* qualified men was detrimental both to professional and public interests and reduced the dentist to the position of a dividend making machine.

The committee then adjourned.

company. If owing to negligence the persons employed by the company to prescribe or attend to patients or to perform dental or other operations were negligent and rendered the company liable to damages there is no substantial person to sue; and it surely was never the intention of the Legislature that the privilege of carrying on business with limited liability should be enjoyed by persons who thus sheltered themselves from the liability which attaches to the individual practitioner. Then, again, practice by joint stock companies encouraged greatly the objectionable practice known as "covering." A qualified medical practitioner might be included among the shareholders or employed as manager by the company; but as these companies usually advertised extensively and carry on business at many different places they almost always employed a number of unqualified persons who sheltered themselves under the name of the qualified employee, and are "covered" (as it was termed) by him. The offence of "covering" was one difficult to prove even in the case of individuals, and it was much more difficult in the case of companies. It was submitted that joint stock companies should be prohibited from carrying on medical or dental practice, simply on the ground that it was an abuse of the Acts to use them for this purpose. The machinery of the Joint Stock Companies Acts, Mr. TOMES further submitted, might as reasonably be applied to the performance of the duties of a barrister or solicitor or a clerk in holy orders as to those of a medical man or dental surgeon. The fact, however, that medical and dental practice by companies led to serious evasions of the Medical and Dentists Acts, and exposed ignorant and poor people to serious risks was, it was submitted, a conclusive argument in favour of these Bills. It only remained to give a few concrete examples which had actually occurred in recent years, which showed conclusively that these evils were not imaginary or slight. In June, 1904, the Registrar of Joint Stock Companies furnished to the House of Commons, at the instance of Sir JOHN TUKE, a return of the companies registered under the Companies Act for the specific purpose of carrying on medical and dental practice. The witness handed in this return. He proceeded to state that while many of these companies were instances of the abuse of the Joint Stock Companies Acts as previously described, the return included some *bonâ fide* companies incorporated for a legitimate purpose, while it did not include many of the most pernicious companies because there was nothing in their titles and often nothing in the description of the business they were avowedly formed to carry on to indicate their real character. In February, 1905, the Registrar of the General Medical Council forwarded to the Privy Council Office, at the request of the Lord President, particulars of various medical and dental companies registered under the Joint Stock Companies Acts which offered professional advice to the public, but which were not included in the Parliamentary return. The operations of not a few of these companies had been before the courts, or had been the subject of inquiries before coroners, or had been brought before the General Medical Council in their judicial capacity. In conclusion, he stated that in June, 1902, a firm of company registration agents issued a circular very extensively pointing out the advantages to be secured by persons not licensed under the Dental Acts by carrying on their business in the form of limited companies, by which "the prohibitive conditions of the Dental Acts may be entirely avoided."

Lord LUDLOW: At present there is no liability on unqualified persons at all?

Mr. TOMES: The unqualified person cannot recover fees.

Lord LUDLOW: There are no liabilities on the unqualified person who sets up practice.

Mr. TOMES: Unfortunately not. There is, of course, the prohibition to use a medical title.

Lord LUDLOW: Under the Bill dealing with dental companies qualified persons would have the right to form a dental company.

Mr. TOMES: I do not think that they would do it

Lord LUDLOW: At any rate, they would have the right to do it.

In answer to Lord KNUTSFORD, Mr. TOMES admitted that the main object of the General Medical Council in promoting these Bills was to place companies in the same position as private individuals who were unqualified.

Lord KNUTSFORD: Would the Council be satisfied if a short clause were enacted saying that the word "person" in the Act of 1858 would include companies?

Mr. TOMES: It would prefer provisions like those in the Bill which has been very carefully considered. These companies have been formed for an illegitimate purpose.

Lord KNUTSFORD: If you extend your powers against companies, why have you not asked further powers against unqualified persons to prevent them acting?

Mr. TOMES: Owing to the difficulty of getting legislation through. In every British colony I may say that unqualified practice is prohibited.

Dr. DONALD MACALISTER, Principal of the University of Glasgow and President of the General Medical Council, was the next witness. He said that he concurred in all particulars in the statement of the Council's views which had just been submitted to the committee by Mr. Tomes. He ought to say at the outset that this matter of unqualified practice by means of companies had been engaging the serious attention of the General Medical Council for ten years. The abuses which were occurring by this company practice were brought to the notice of the Council by the occurrence of particular cases which it attempted to check by the machinery of the Medical Acts, but it was unable to do so owing to the decision of the House of Lords referred to in the statement submitted by Mr. Tomes. A company was not a "person" and could not be restrained in the same way as an individual unqualified person. He felt strongly that the Companies Acts were being grossly abused in affording protection to unqualified persons. An unqualified individual might practise. There was nothing to prevent him. However, there were certain things that he could not do. He could not call himself a surgeon, a dentist, or a physician. He could not sign medical certificates, nor could he hold a public appointment. He was not exempted from various civic liabilities as surgeons and physicians were. The company, however, gave certain protection to unqualified men. It was limited in its liability to the amount of its shares, supposing malpractices were found against it and damages were awarded. The damages could not exceed the amount of the shares. He had found also that the sanction granted by the present state of the law to unqualified persons through the companies had a serious effect as regarded their dealings with the public. The Companies Acts were not intended for any other purpose than to afford financial encouragement for legitimate industry, and he could not think they were intended to give their quasi-legal status to a body of persons who could not otherwise exercise the functions of the medical profession. That was the view which Lord Halsbury took when he included clauses on this subject in his Bill of 1900. That Bill set forth that it should be unlawful for a company to carry on the profession or business of a surgeon, physician, dentist, or midwife. These clauses were struck out in the House of Commons on the ground that they were not germane to the other purposes of a Companies Bill. No objection was taken to them on principle.

The CHAIRMAN: I think that successive Governments, through the Presidents of the Council of the day, have never offered any opposition to your endeavours to get measures of this kind passed?

Dr. MACALISTER: I should be able, if your lordships desire it, to lay before you certain communications from the law officers of the Crown urging the General Medical Council to bring this matter forward.

The CHAIRMAN: I think we should like a return of that correspondence. Now, Dr. MacAlister, have you any concrete cases to put before the committee?

Dr. MACALISTER: The number of concrete cases with regard to medical practice is smaller than is the case with dental. There had been on several occasions threats on the part of persons who had been struck off the Medical Register for disgraceful and infamous conduct in a professional respect to go into practice again as a company and so defy the Council.

The CHAIRMAN: You want to prevent the materialisation of these threats?

Dr. MACALISTER said that they were rarely or never carried out. The General Medical Council exercises the power of putting a man back on the Register. He pointed out in these cases that any such action as that threatened would be a final bar to the restoration of the offending practitioner. That had been successful and they had heard no more of the threats. He thought that in one or two cases the practitioner had restored himself to good repute. The General Medical Council had used its powers more for preventive purposes than for punitive. As regarded unqualified persons who had taken medical titles there was the case of I. Waters and Sons, Limited, which was registered in 1897 in Dublin to carry on (*inter alia*) the business of physicians and surgeons. The subscribers were six members of the Waters family (three of them ladies) and a solicitor. There was no qualified practitioner among the signatories. The World's Dispensary Medical Association was another similar case. Of the seven subscribers six had the letters M.D. after their names and the other was described as superintendent. All had addresses in the United States except one, who is described as living in London. None of these names were on the Medical Register and none were legally qualified to practise pharmacy. This company was wound up in 1900. There was also the case of the "Dr. Bland" Company, Limited. This company was registered in April, 1899, in Dublin, the object being to carry on or practise the profession or business of medical doctors, physicians, surgeons, apothecaries, pharmaceutical chemists, dentists, midwives, and dry-goods and patent medicine vendors. There was no such person as Dr. Bland registered as resident in Ireland.

The CHAIRMAN: Is it not the case that the poorer classes are liable to be deceived in medical matters by companies?

Dr. MACALISTER: The poorer classes are deceived. The information which has come to the General Medical Council proves it. Circulars had been issued broadcast advertising these companies. He would like to direct the attention of the committee to the case of the General Council of Safe Medicine, Limited. This company was limited by guarantee, each member being liable for not more than £5. The company had therefore no capital. Its object was to grant degrees, scholarships, &c., in the magnetic and botanic system of Safe Medicine, the highest diploma conferring the distinction of Doctor of Botanic Medicine—distinguished by the letters M.D. (b.c.). The subscribers were a clergyman, a merchant, and five persons describing themselves as medical herbalists. On August 8th, 1894, proceedings were taken against the company and 14 managers by the Attorney-General at the relation of the General Medical Council and the company and managers submitted to an injunction restraining them from issuing or conferring any degree or diploma of M.D. (b.c.) or other like degree or diploma purporting to qualify or authorise any person to treat disease. The General Medical Council objected to the machinery of the Board of Trade being called into play to give a quasi-legal sanction to companies which were bogus companies and frauds.

Lord LUDLOW: A company might be formed of qualified persons to carry on business as medical men. Would you object to that?

Dr. MACALISTER: I would only say that the point has not been brought before me. It seems to be against the public interest that the law should step in to limit their liability. There should be a personal responsibility to the public maintained.

The CHAIRMAN: You hold the personal responsibility of the medical man would be weakened if he were in a company?

Dr. MACALISTER: I do. He further admitted, in answer to Lord KNUTSFORD, that the Bill with regard to medical companies incidentally prevented the qualified men from forming a company. He thought, however, that it was good that seven qualified men should not form a company because that would limit their pecuniary liability.

Lord KNUTSFORD: It appears to me that this Bill would prevent two men both qualified carrying on business in company.

Dr. MACALISTER: It would prevent them carrying it on as a limited liability company but not from carrying it on in partnership.

Lord FALKLAND: Do you know of a case of qualified medical men or dentists forming themselves into a company?

Dr. MACALISTER: I have never heard of one. None has come to our notice. He went on to say that he wished to emphasise the danger which had arisen from the abuse of the machinery of the Companies Acts. If he would quote a circular which had been issued by a firm of company registration agents the committee would see what he meant. It ran as follows:—

"*Private and Confidential.*

"DEAR SIR,—You may possibly be aware that there are rumours of further stringent legislation in connexion with the carrying on of businesses allied to dentistry ('artificial teeth manufacturing,' &c.) by persons not licensed under the *Dental Acts* and we take the opportunity of pointing out to you that numerous and important advantages may be secured by carrying on such businesses in the *form*

INDIAN MEDICAL SERVICE.—An Examination for not less than 11 Commissions.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

LEEDS TUBERCULOSIS ASSOCIATION SANATORIUM, Gateforth, near Selby.—Resident Medical Officer for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

LEICESTER INFIRMARY.—Assistant House Physician for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

LEYTONSTONE, N., WEST HAM UNION INFIRMARY, Whipps Cross-road.—Junior Assistant Medical Officer. Salary £100 per annum, rising to £120, with the usual residential allowances.

LIVERPOOL WORKHOUSE, Brownlow-hill.—Assistant Medical Officer. Salary £100 per annum, with apartments and rations.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60, with board and lodging.

MANCHESTER, UNIVERSITY OF.—Junior Demonstrator of Physiology. Salary £100, rising to £150 per annum.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Honorary District Medical Officers.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Senior and Junior House Physicians. Salary £50 per annum, with board and residence in each case.

NEWCASTLE-UPON-TYNE, CITY AND COUNTY OF.—Assistant Medical Officer of Health and Resident Medical Officer of the City Hospital for Infectious Diseases, unmarried. Salary £300 per annum, with board, lodging, &c.

NEW HOSPITAL FOR WOMEN, Euston-road, N.W.—Senior Obstetric Assistant, Anæsthetist, and Clinical Assistant (all females).

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and laundry.

MOIR.—At Calcutta, on June 5th, Major David Macbeth Moir, M.A., M.D., I.M.S., Professor of Anatomy, Medical College, Calcutta, eldest son of the late Dr. Moir, St. Andrews.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AN UNUSUAL DRUG HABIT.

A VERY strong drug habit in a youth aged 20 years brought its victim before the Leyton magistrates on May 27th charged with obtaining methylated chloroform from medical men under false pretences. He had displayed considerable ingenuity in obtaining the drug, with which the druggists in the district had been forbidden by the boy's father to supply him. He first went to Mr. A. W. Aldrich of Leyton and stated that he was a medical student and Mr. E. R. Dawson's nephew, that the latter had exhausted his stock of chloroform and needed two ounces at once for an operation, and Mr. Aldrich accordingly let him have that amount. He then proceeded to visit Dr. J. O. Goldie, and stating that he was dispenser to a neighbouring practitioner he preferred a similar request and obtained another ounce of chloroform. An hour later he posed as Dr. Goldie's dispenser and called on Mr. W. G. Noble for a loan of the drug on his "employer's" behalf. Mr. Noble happened to know that Dr. Goldie did not keep a dispenser and sent for that gentleman to confront the youthful impostor who subsequently pleaded guilty, saying that he had taken chloroform for many years and was not in his right mind on the day in question on account of the amount which he had taken; he took it as a *habit* and not to relieve pain. The boy's father said that his son had taken the drug since he was 14 years old and had obtained it in a similar way before and that he had been examined by "doctors and specialists." The chairman remarked that the case required special treatment and remanded the young man to be examined medically.

A NEGLECTED TEXT.

To the Editors of THE LANCET.

SIRS,—Having read "M.D.'s" letter (THE LANCET, May 11th) with regard to the above and also the answer (if it may be called an answer) of "Soberness" (THE LANCET, May 25th), may I be permitted to take up some of your valuable space with another Biblical quotation which appears to me to be particularly applicable. I am more especially urged to draw the attention of your readers to it as I have known cases where the relatives of patients (members of a particular friendly society) have refused to administer alcohol, presumably on religious grounds, although both a colleague and myself considered it necessary. I refer to Proverbs xxxi. 6 and 7: "Give strong drink unto him that is ready to perish, and wine unto those that be of heavy hearts. Let him drink and forget his poverty and remember his misery no more." I think that any reasonable person must admit that the text not only sanctions but also advocates the use of alcoholic beverages as medical remedies.

I am, Sirs, yours faithfully,

Radstock, Bath, May 28th, 1907. JOHN PRATT.

To the Editors of THE LANCET.

SIRS,—Your correspondent "M.D." would never have wondered at all why the sentence Judges ix. 12, 13 had been so neglected unless he considered that "this striking sentence" was a striking support of the drinking of wine and intoxicating liquor in moderation. As this inference from his words is the real reason why he wrote, surely it is not impolite to reverse it by pointing out to him the facts which have been omitted by him in arriving at it. If "Cedar" had read my letter carefully he would have seen that I was not pointing out the historical meaning of Jotham, for I expressly mentioned that Jotham meant in Hebrew "Yah is perfect" (see Dr. Young's Concordance). What I desired to emphasise was this, that the account of Jotham and his parable and doings could be regarded as a parable uttered by the voice of personified *dirt* which dwelt at the well whose contents were *beer* and *be-err*, and that from this point of view it failed to exhibit that moral and spiritual perfection and thoroughness which we expect in a true revelation concerning the character of God such as *this*, to wit, that wine cheereth God, and that in consequence it condemned rather than sanctioned the use of wine and intoxicating liquor in moderation. I may point out that this position has not been undermined by "Cedar." This account of Jotham, in fact, is a perfect example of a wolf masquerading in sheep's clothing or of uncleanliness putting on a fair historical appearance. It is also an example of the historical letter which killeth and of the spirit which giveth life, which is the spirit of interpretation and

Yours sincerely,

May 31st, 1907. SOBERNESS.

NEW QUARTZ LAMP FOR TREATMENT BY ULTRA-VIOLET RAYS.

MESSRS. H. W. COX, Limited, of 1A, Rosebery-avenue, have brought to our notice a new quartz lamp for the light treatment of lupus, &c. In this lamp mercury vapour is enclosed in a hermetically sealed transparent tube made of rock crystal. The lamp is brought into incandescence by means of the electric current. Quartz being completely transparent to ultra-violet rays the quantity evolved is greatly increased, besides which quartz will stand a much higher temperature than glass and so the mercury vapour can be brought to a higher degree of incandescence. It is stated that the exposure required

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) *is published in time to catch the weekly Friday mails* to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable *in advance.* Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Daily Mail (Hull), Morning Post, Newcastle Chronicle, Notts Guardian, Birmingham Gazette, Derby Express, Manchester Despatch, Bradford Daily Argus, Midland Evening News, Pharmaceutical Journal, Bath Chronicle, Grimsby Gazette, Sheffield Telegraph, Evening News, Edinburgh Evening News, Cornish Times, Veterinary Record, Schoolmaster, Bristol Echo, Morning Leader, Daily Chronicle, Worcester Times, Western Mercury, Scientific American, &c.*

when using this lamp is half the time of that required by the "iron" light and from a third to a fifth of that taken by the Finsen light. It is capable also of dealing with larger areas.

CRYSTALLINE CALOMEL.

To the Editors of THE LANCET.

SIRS,—I am taking the liberty of sending you a *specimen of* a crystalline modification of calomel first isolated by Meyer in 1905 which I have been using *for some time now in preference to* the ordinary varieties for diseases of the eye. It is prepared by adding a solution of lithium sulphite *to one of* mercuric chloride. The heavy white precipitate of ordinary calomel is filtered off and the clear solution heated to from 70° to 80° C., when the salt separates in lustrous scales. It has a specific gravity of from 4·5 to 5·0, as against from 6·5 to 7·0 of the ordinary salt, and it changes into the latter on sublimation. It does not seem to be an allotropic modification, as it shows no difference of potential when measured in a galvanic cell against ordinary mercurous chloride. The salt was prepared *for me by Mr.* Martindale, of 10, New Cavendish-street, London, W., whom I have to thank for the trouble taken in its preparation and *from whom it may* be obtained by those who are interested in the new salt.

I am, Sirs, yours faithfully,

May 28th, 1907. J. BURDON-COOPER, M.B., B.Sc., F.R.C.S.

Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (13th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

FRIDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (15th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (11th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M.: Mr. P. L. Mummery: The Causes of Colitis, with Special Reference to its Surgical Treatment, with an Account of Thirty-six Cases.—Dr. D. Forsyth: Experiments on Prolonged Protein Feeding, with Special Reference to the Thyroid *Glands and the Production of Osseous Tissue.*—Dr. N. Bardswell and Dr. J. E. Chapman: The Changes occurring in the Number of Red Corpuscles and their *Hæmoglobin Contents* in Pulmonary Tuberculosis. (Epidiascope demonstration.)

WEDNESDAY (12th).—*DERMATOLOGICAL SOCIETY OF LONDON* (11, Chandos-street, Cavendish-square, W.).—4.30 P.M.: Special General Meeting for the purpose of Dissolving the Society and Merging it into the Royal Society of Medicine.

SOUTH-WEST LONDON MEDICAL SOCIETY (Head-quarters of the 4th Volunteer Battalion, East Surrey Regiment (opposite Clapham Junction Station)—9 P.M.: Annual Bolingbroke Lecture:—Dr. G. H. Savage: *The Factors of Insanity.*

THURSDAY (13th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM *(11, Chandos-street, Cavendish-square, W.).—8 P.M.:* Card Specimens. 8.30 P.M.: Papers:—Mr. Nettleship: A History of Night Blindness in *Nine Consecutive Generations.—Mr. L. Werner:* A Peculiar Case of Subretinal Cysticercus.—Mr. A. L. Whitehead: (1) A Metastatic Tumour of the Choroid; (2) Multiple Cysts of Retina.

FRIDAY (14th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—6 P.M.: Bowman Lecture: Prof. Sattler: The Pathology and Treatment of Myopia.

SATURDAY (15th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (County Hospital, Bedford).—3 P.M.: Discussion on Acute Rheumatism (opened by Dr. C. O. Hawthorne). *Papers by* Dr. E. Cautley and Mr. Tubby.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (10th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—12 noon: Pathological Demonstration. 2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Mr. Baldwin: *Practical Surgery.*

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. C. Fox: Clinique. (Skin.) 5.15 P.M. Lecture:—Dr. T. W. Eden: The Early Treatment of Puerperal Infection.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Cliniques:—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: *Medical Out-patient* (Dr. Whipham); Throat, Nose, and Ear (Mr. Carson); X Ray (Dr. Pirie).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Sir Dyce Duckworth: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. StClair Thomson: Diseases of the Throat, Nose, and Ear. Out-patient Demonstrations:—10 A.M.: Surgical and Medical. 12 noon: *Ear* and Throat. 3.15 P.M.: Special Lecture:—Mr. W. Turner: Empyema.

ROYAL INSTITUTE OF PUBLIC HEALTH (20, Hanover-square, W.).—6 P.M.: *Harben Lecture: Prof. Dr. P.* Ehrlich: Experimental Researches on Specific Therapeutics.

TUESDAY (11th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynæcological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: *Operations.* Dr. Abraham: Diseases of the Skin. 5 P.M.: Lecture:—Dr. Low: Ankylostomiasis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, *W.C.).—4 P.M.: Dr. B Abrahams:* Clinique. (Medical.) 5.15 P.M.: Lecture:—Dr. D. Grant: The Treatment, especially Conservative, of Chronic Suppuration of the Middle Ear.

NORTH-EAST LONDON POST-GRADUATE COLLEGE *(Prince of Wales's* General Hospital, Tottenham, N.).—Cliniques:—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: *Gynæcological Out-patient* (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (*Mr. Carson*). 4.30 P.M.: Special Demonstration of Cases (Mr. Carson).

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.15 P.M.: Dr. R. T. Hewlett: Medicine. 2.30 P.M.: Operations. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient *Demonstrations*:—10 A.M.: Surgical and Medical. 12 noon: Skin.

ROYAL INSTITUTE OF PUBLIC HEALTH (20, Hanover-square, W.).—6 P.M.: Harben Lecture: Prof. Dr. P. Ehrlich: Experimental Researches on Specific Therapeutics.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—3.45 P.M.: Demonstration:—Dr. D. Grant: Methods of Examination.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. Ormerod: Friedreich's Disease.

WEDNESDAY (12th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X *Rays.* Mr. K. Scott: Diseases of the Eye. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Dr. Beddard: *Practical Medicine.*

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. C. Ryall: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Mr. L. Cheatle: *Paget's Disease of the Nipple and its* Treatment (with lantern slides).

The Ingleby Lectures

ON

PELVIC INFLAMMATIONS IN THE FEMALE.

Delivered at the University, Birmingham, on May 9th and 16th, 1907,

BY THOMAS WILSON, M.D. LOND., M.CH. BIRM., F.R.C.S. ENG.,
OBSTETRIC OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM.

LECTURE I.

Delivered on May 9th.

MR. DEAN AND GENTLEMEN,—The Ingleby Lectures were established in connexion with Queen's College in the year 1876 and were intended to promote "the advancement of obstetric medicine and surgery, including diseases of women and children, being a branch of medical science in which Dr. John Tomlinson Ingleby acquired considerable reputation." Dr. Ingleby practised in Birmingham from the year 1816 until his death at the end of January, 1845. The writer of an eloquent and appreciative obituary notice tells us that death resulted from pneumonia, for which it is interesting as showing the difference between the treatment of inflammations then and now to note that blood was taken to the amount of a pint from the arm, leeches were applied to the head, followed by a blister and a cathartic of colocynth, and small doses of calomel at short intervals. Two days after the acute onset of the pneumonia the patient was seized with intense headache, for which effusions of cold water were used, followed by leeches to the side of the head, and other remedies; delirium followed, and the patient died on the fifth day from the onset of the pneumonia. Post-mortem examination disclosed pleurisy on the right side and meningitis. The writer in his summary states that "from beginning to end the case was clearly one of metastatic gout, altering its features with the several organs it visited, but uniformly distinguishing itself by the characteristics of specific inflammation." In the light of present-day knowledge it is probable that the cause of death was a terminal infection by the pneumococcus.

Dr. Ingleby completed his fiftieth year shortly before his death, "a victim to the undue devotion to study and to the duties of his immense practice." He was the first specialist in obstetric medicine in Birmingham, and lectured on midwifery when the medical school was first formed in this city in 1828. He was one of the original members of the still flourishing Medical Benevolent Society, and it is good evidence of the esteem in which he was held by his professional brethren that, as I am informed by Mr. W. F. Haslam, he was appointed president of the society in 1836. As an author on obstetric subjects Dr. Ingleby was without a provincial rival, and his writings, as Dr. C. J. Cullingworth has remarked, were evidently the outcome of close personal observation and of a sound judgment, and appear to have fairly reflected the best opinions and the best practice of the time. Among several papers by Dr. Ingleby, published in the *Edinburgh Medical and Surgical Journal*, is one in relation to the subject of these lectures in Vol. XLIX. for 1838, in which he relates several epidemics of puerperal fever which occurred in Birmingham in the years 1826, 1833, and later. In this paper the author insists upon the great contagiousness of the affection, and recognises the fact that erysipelas and puerperal fever may both be due to the same morbid poison. He refers to the then recent researches of Dr. Robert Lee on the morbid anatomy of puerperal fever.

At that time scientific knowledge of pelvic inflammations was rudimentary and it was not until the second half of the century that a deeper insight began to be obtained into the nature of inflammation in general and those of the uterine appendages in particular. After Dr. Lee's researches the next important work appears to have been that of Bernutz and Goupil, who, in 1857, first made known to the profession that gonorrhœa frequently gives rise to severe inflammation of the uterine appendages and pelvic peritoneum. In 1872 Noeggerath, in an epoch-making paper, emphasised with some pardonable exaggeration the wide-spread and disastrous effects produced by gonorrhœa on the female pelvic organs. In 1879 the gonococcus was discovered by Neisser. About this time the development of modern surgery began to pave the way for a fuller knowledge of these affections and among the earliest workers in this field the name of our late fellow-townsman, Lawson Tait, stands conspicuous. In the early "eighties" Tait on many occasions brought before the Pathological and Obstetrical Societies papers on, and specimens of, pyosalpinx removed by operation from patients in whom they had been the cause of grave persistent illnesses.

Like all other leaders of men Lawson Tait not merely drew to himself a large following of disciples and believers, but excited among the more conservative members of the profession a determined opposition. He was not long in gaining support from the pathological side. In 1884 J. K. Fowler read a paper before the Medical Society of London in which he related 15 cases of diseases of the uterine appendages occurring in the post-mortem room at the Middlesex Hospital in the preceding three years. In at least seven of the cases death had resulted from the condition, in several of them from ruptured pyosalpinx; while testimony to the severe and long-continued exhausting illness which may result from pyosalpinx is found in the fact that two of the patients died with amyloid disease of the viscera. Three years later Lewers at the Obstetrical Society related his observations on 100 post-mortem examinations of female patients at the London Hospital; he had found pyosalpinx in five of the cases, hæmatosalpinx in four, and hydrosalpinx alone or combined with pyo- or hæmato-salpinx in eight. A few years later, in 1892, Cullingworth read a paper at the same society on the value of abdominal section in certain cases of pelvic peritonitis, based on a personal experience of 50 cases; and since this time it has been universally recognised by the profession in this country that surgical treatment is not only justifiable but of the greatest value in certain inflammations of the uterine appendages.

Formerly pelvic inflammation could only be studied at the bedside and in the post-mortem room. Now abundant material is provided by the numerous operations performed for these affections and frequent opportunities are afforded for comparing the results of clinical examination with the actual conditions present in the diseased organs. In the investigation the aid of the microscope, of chemistry, and of bacteriology is invoked, and in the last few years a further great impetus has been given to the research by the development of bio-chemical methods. At the present time a case of pelvic inflammation demands not merely the use of all the time-honoured methods of clinical examination, subjective and objective, but calls for the employment by specially skilled observers of chemical and bacteriological methods of determining the characters of the blood, of the discharges, and of fluids and tissues which may be removed either during the life or after the death of the patient.

At a large general hospital such as the one to which I have the honour to be attached abundant opportunities are presented of studying pelvic inflammations in the female in all stages and degrees of severity. Among the out-patients in the special department for diseases of women are seen the slighter cases that are amenable to simpler methods of treatment. Here 1 patient in every 8 is affected by inflammation of the pelvic peritoneum or cellular tissue or of the uterine appendages. In a consecutive series of 8714 special cases of diseases of women seen by me 1092 (12·5 per cent.) applied for treatment for these affections. The diagnosis of the various conditions observed was as follows:—

Acute pelvic cellulitis	70
Subacute or chronic cellulitis	43
Acute inflammations complicating pregnancy	4
Acute pelvic peritonitis	258
Suppurative peritonitis	4
Tuberculous peritonitis	27
Chronic pelvic peritonitis	151
Salpingitis	85
Salpingo-ovaritis	217
Ovaritis	223
Adherent retroversion of the uterus	29
Total	1092

These headings represent merely working clinical diagnoses and as in the great majority of the patients recovery, partial or complete, has taken place without operation—that is to say, without the opportunity of actually inspecting the affected organs—it has not seemed necessary or even useful further to analyse the cases upon this occasion.

In the post-mortem room we are able to see the end result of the affections in the worst cases, and for this purpose I

Communications, Letters, &c., have been received from—

A.—Asylums Committee of the London County Council; Association of Medical Diplomates of Scotland, Hon. Secretary of; Messrs. Aked and Aked, Lond.; American Medical Association, Chicago.

B.—Mr. W. Bernard, Buncrana; Messrs. Burroughs, Wellcome, and Co., Lond.; *Dr. J. B. Ball, Lond.*; Dr. Carnegie Brown; Mr. B. H. Blackwall, Oxford; Mr. H. Norman Barnett, Belfast; Mr. C. Birchall, Liverpool; Brighton, &c., Dispensary, Secretary of; Dr. C. S. Bond, Lond.; Colonel S. H. Browne, I.M.S., Newcastle, Ireland; *Major* Blackham, R.A.M.C., Devonport; British Medical Association, Metropolitan Counties Branch, President of; Bristol General Hospital, Secretary of; Mr. E. Bedford, Newhaven; Mr. R. *Bilton, Rudyard*; *Buxton Herald*, Editor and Manager of; British Medical Benevolent Fund, Lond., Hon. Secretary of; Brighton and *Hove Dispensary, Secretary of*; Bristol Myers Co., New York; Mr. A. C. Bamlett, Thirsk; Birmingham University, Clerk to the.

C.—Mr. Herbert Carson, Lond.; Messrs. J. and A. Carter, Lond.; Cottage Benefit Nursing Association, *Lond., Hon. Secretary of*; Mr. F. W. Clarke, Chorlton-cum-Hardy; Dr. H. Campbell, Lond.; *Canterbury Borough* Asylum, Medical Superintendent of; Cameron Hospital, West Hartlepool, Secretary of; Mr. W. Coles, Watford; Coventry and Warwickshire Hospital, Secretary of; Central News, Lond., Manager of; Mr. J. F. Colyer, Lond.; Messrs. J. and A. Churchill, Lond.; *C. W. N.*; *Dr. H. The Ingleby Lectures

ON

PELVIC INFLAMMATIONS IN THE FEMALE.

Delivered at the University, Birmingham, on May 9th and 16th, 1907,

BY THOMAS WILSON, M.D. LOND., M.CH. BIRM., F.R.C.S. ENG.,

OBSTETRIC OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM.

LECTURE I.

Delivered on May 9th.

MR. DEAN AND GENTLEMEN,—The Ingleby Lectures were established in connexion with Queen's College in the year 1876 and were intended to promote "the advancement of obstetric medicine and surgery, including diseases of women and children, being a branch of medical science in which Dr. John Tomlinson Ingleby acquired considerable reputation." Dr. Ingleby practised in Birmingham from the year 1816 until his death at the end of January, 1845. The writer of an eloquent and appreciative obituary notice tells us that death resulted from pneumonia, for which it is interesting as showing the difference between the treatment of inflammations then and now to note that blood was taken to the amount of a pint from the arm, leeches were applied to the head, followed by a blister and a cathartic of colocynth, and small doses of calomel at short intervals. Two days after the acute onset of the pneumonia the patient was seized with intense headache, for which effusions of cold water were used, followed by leeches to the side of the head, and other remedies; delirium followed, and the patient died on the fifth day from the onset of the pneumonia Post-mortem examination disclosed pleurisy on the right side and meningitis. The writer in his summary states that "from beginning to end the case was clearly one of metastatic gout, altering its features with the several organs it visited, but uniformly distinguishing itself by the characteristics of specific inflammation" In the light of present-day knowledge it is probable that the cause of death was a terminal infection by the pneumococcus.

Dr. Ingleby completed his fiftieth year shortly before his death, "a victim to the undue devotion to study and to the duties of his immense practice." He was the first specialist in obstetric medicine in Birmingham, and lectured on midwifery when the medical school was first formed in this city in 1828. He was one of the original members of the still flourishing Medical Benevolent Society, and it is good evidence of the esteem in which he was held by his professional brethren that, as I am informed by Mr. W. F. Haslam, he was appointed president of the society in 1836. As an author on obstetric subjects Dr. Ingleby was without a provincial rival, and his writings, as Dr. C. J. Cullingworth has remarked, were evidently the outcome of close personal observation and of a sound judgment, and appear to have fairly reflected the best opinions and the best practice of the time. Among several papers by Dr. Ingleby, published in the *Edinburgh Medical and Surgical Journal*, is one in relation to the subject of these lectures in Vol. XLIX. for 1838, in which he relates several epidemics of puerperal fever which occurred in Birmingham in the years 1826, 1833, and later. In this paper the author insists upon the great contagiousness of the affection, and recognises the fact that erysipelas and puerperal fever may both be due to the same morbid poison. He refers to the then recent researches of Dr. Robert Lee on the morbid anatomy of puerperal fever.

At that time scientific knowledge of pelvic inflammations was rudimentary and it was not until the second half of the century that a deeper insight began to be obtained into the nature of inflammation in general and those of the uterine appendages in particular. After Dr. Lee's researches the next important work appears to have been that of Bernutz and Goupil, who, in 1857, first made known to the profession that gonorrhœa frequently gives rise to severe inflammation of the uterine appendages and pelvic peritoneum. In 1872 Noeggerath, in an epoch-making paper, emphasised with some pardonable exaggeration the wide-spread and disastrous effects produced by gonorrhœa on the female pelvic organs. In 1879 the gonococcus was discovered by Neisser. About this time the development of modern surgery began to pave the way for a fuller knowledge of these affections and among the earliest workers in this field the name of our late fellow-townsman, Lawson Tait, stands conspicuous. In the early "eighties" Tait on many occasions brought before the Pathological and Obstetrical Societies papers on, and specimens of, pyosalpinx removed by operation from patients in whom they had been the cause of grave persistent illnesses.

Like all other leaders of men Lawson Tait not merely drew to himself a large following of disciples and believers, but excited among the more conservative members of the profession a determined opposition. He was not long in gaining support from the pathological side. In 1884 J. K. Fowler read a paper before the Medical Society of London in which he related 15 cases of diseases of the uterine appendages occurring in the post-mortem room at the Middlesex Hospital in the preceding three years. In at least seven of the cases death had resulted from the condition, in several of them from ruptured pyosalpinx; while testimony to the severe and long-continued exhausting illness which may result from pyosalpinx is found in the fact that two of the patients died with amyloid disease of the viscera. Three years later Lewers at the Obstetrical Society related his observations on 100 post-mortem examinations of female patients at the London Hospital; he had found pyosalpinx in five of the cases, hæmatosalpinx in four, and hydrosalpinx alone or combined with pyo- or hæmato-salpinx in eight. A few years later, in 1892, Cullingworth read a paper at the same society on the value of abdominal section in certain cases of pelvic peritonitis, based on a personal experience of 50 cases; and since this time it has been universally recognised by the profession in this country that surgical treatment is not only justifiable but of the greatest value in certain inflammations of the uterine appendages.

Formerly pelvic inflammation could only be studied at the bedside and in the post-mortem room. Now abundant material is provided by the numerous operations performed for these affections and frequent opportunities are afforded for comparing the results of clinical examination with the actual conditions present in the diseased organs. In the investigation the aid of the microscope, of chemistry, and of bacteriology is invoked, and in the last few years a further great impetus has been given to the research by the development of bio-chemical methods. At the present time a case of pelvic inflammation demands not merely the use of all the time-honoured methods of clinical examination, subjective and objective, but calls for the employment by specially skilled observers of chemical and bacteriological methods of determining the characters of the blood, of the discharges, and of fluids and tissues which may be removed either during the life or after the death of the patient.

At a large general hospital such as the one to which I have the honour to be attached abundant opportunities are presented of studying pelvic inflammations in the female in all stages and degrees of severity. Among the out-patients in the special department for diseases of women are seen the slighter cases that are amenable to simpler methods of treatment. Here 1 patient in every 8 is affected by inflammation of the pelvic peritoneum or cellular tissue or of the uterine appendages. In a consecutive series of 8714 special cases of diseases of women seen by me 1092 (12·5 per cent.) applied for treatment for these affections. The diagnosis of the various conditions observed was as follows:—

Acute pelvic cellulitis	70
Subacute or chronic cellulitis	43
Acute inflammations complicating pregnancy ..	4
Acute pelvic peritonitis	258
Suppurative peritonitis	4
Tuberculous peritonitis	27
Chronic pelvic peritonitis	131
Salpingitis	86
Salpingo-ovaritis	217
Ovaritis	223
Adherent retroversion of the uterus	29
Total	1092

These headings represent merely working clinical diagnoses and as in the great majority of the patients recovery, partial or complete, has taken place without operation—that is to say, without the opportunity of actually inspecting the affected organs—it has not seemed necessary or even useful further to analyse the cases upon this occasion.

In the post-mortem room we are able to see the end result of the affections in the worst cases, and for this purpose I have examined the records of 1487 consecutive necropsies on females that have been made in the General Hospital from 1891 until the middle of the year 1906. The notes vary much in value according to the attention paid to the pelvic organs by the pathologist for the time being but abundant evidence is afforded of the frequency and gravity of the affections we are considering. Secondary infections of the Fallopian tubes of merely pathological interest are frequently observed, as in cases of perforative peritonitis from various causes where the resulting exudation invades the open fimbriated extremities; in patients dying from tuberculous affections, in whom the tubes and pelvic peritoneum are frequently involved; and in women dying from cardiac diseases, in whom catarrhal salpingitis is common. Cases in which death is directly brought about by diseases arising in the generative organs are also common enough. The affections may be fatal in the acute stage from septicæmia, pyæmia, or peritonitis, or in the later stages from rupture, or perforation and peritonitis, or from intestinal obstruction. The most frequent cause of death in the earlier stages is puerperal infection and in the present series are included 22 such cases. One patient died from thrombosis of the inferior vena cava arising from a pelvic peritonitis. In four patients acute gonorrhœal peritonitis, and in one patient gonorrhœal pyæmia, caused death. The fatal issue may result after a long period has elapsed, sometimes many years after the originating infection. Thus fatal peritonitis was caused by rupture of a pyosalpinx in seven instances and of an ovarian abscess in two, while saprophytic infection of an old tuberculous pyosalpinx led to the death of another patient. In 17 cases intestinal obstruction was set up by bands having one end attached to the uterus or its appendages; in five of these there had been previous operations on the pelvic organs, in the other 12 none. In two cases it is noted that hydronephrosis had arisen from pressure on the ureters by pyosalpinx. One of these cases was of peculiar interest; it occurred in a rickety child, aged two and a half years, who died from gonococcal peritonitis; the tubes contained thin pus and the pathologist observes that "it is evidently their pressure that has caused narrowing of the ureters and hydronephrosis." The pus in the tubes contained diplococci, mostly intracellular, not taking Gram's stain. Seven patients died from infection by the pneumococcus, and in six of them it is distinctly stated that the uterus and appendages were healthy; three, however, had been recently delivered, so that it would appear that the puerperal state in some way predisposes to infection by the pneumococcus, but that the invasion does not take place by way of the pelvic organs.

In this account of post-mortem observations on pelvic inflammations in the female I have purposely omitted any reference to the examinations made upon patients dying after gynæcological operations. The cases of intestinal obstruction and of ruptured pyosalpinx referred to came in the ordinary course of emergency operations to my surgical colleagues and the information gained from necropsies on my own patients has been used in the analysis of in-patient cases.

The most acute and severe cases of pelvic inflammation that apply for help are admitted for in-patient treatment, in most instances by operation. In a certain proportion after further observation operative treatment is not considered necessary or is rejected. For the present purpose 38 such cases are not considered, because conclusions to be of service, in my opinion, should be based, not merely upon clinical observation of patients, but also upon a careful investigation at operation or post-mortem examination of the diseased organs. For the purposes of these lectures I have analysed the notes of every case of inflammation of the uterine appendages and of the pelvic peritoneum and cellular tissue that has come under my care for operation in the in-patient department of the General Hospital up to the end of 1906; in most of the cases the necessary surgical treatment has been carried out by myself, but in a certain number the operations have been performed by my colleague, Mr. J. T. Hewetson, and by the resident surgical officers. All my private operations until the same date have been included in the analysis. The total number of cases is 307, in which are included six of puerperal pyæmia and 41 of suppuration of the pelvic cellular tissue.

Pelvic cellulitic abscess.—Of the cases of extraperitoneal abscess one which had existed since the previous labour and had opened into the vagina was complicated by pregnancy; in another patient a small abscess formed between the layers of the outer part of the broad ligament after an abortion; and in a third persistent suppuration of the conne tissue surrounding the supravaginal cervix followed upc operation for removal of the appendages performed where. All the other cases were puerperal, and with exceptions were operated upon within three montl labour. In one patient who was very ill with a third a of acute lateral cellulitis five years had elapsed since th labour, with which the history clearly connected the ab The other exception occurred in a patient two and a years after the last labour; there was no leucocyt through a subperitoneal incision curdy matter in whicl a calcareous nodule was evacuated; the pus contained diplococci growing feebly on agar and staining by G method, but no tubercle bacilli could be found; two mo after the operation there was still a mass behind the ut probably caused by a pyosalpinx. The situation of abscess in these extraperitoneal cases was in the la connective tissue in 31, in the connective tissue behin uterus in eight, and between the layers of the broad liga in two, both verified by abdominal section. In five of cases an exploratory laparotomy was performed and in e instance disclosed adhesions of the appendages on the affected, varying from a few loose membranes to d brawny induration.

Intraperitoneal abscess.—Among the remaining 260 c of pelvic inflammation there were 41 cases of intraperito suppuration, of which 12 associated with pyosalpinx wil considered in that connexion. Of 12 other cases in whi posterior vaginal incision was made, in six the append were made out to be adherent and enlarged; in the other the appendages could not be definitely recognised. 17 ca treated by abdominal incision and drainage included where the uterus had been perforated in curetting for an complete abortion, and four in which the origin of the could not be made out with certainty. In a sixth patient whole pelvis was filled by a dense, hard, inflammatory m containing disseminated small collections of pus and relations to the organs could not be made out. The ot cases occurred in parous patients and had probably origina in the appendages. Of the whole number of 41 in peritoneal abscesses 18 certainly, and 11 more with g probability, had originated in affections of the uterus or adnexa. Of the remaining 12 suppuration had been cau by infected ligatures or infection at a previous opera in five and the pathological relations were obscure in seve Excluding puerperal pyæmia and cellulitic abscess, and s tracting 12 cases of pelvic abscess, some of them of doub origin, it appears that of 260 pelvic inflammations treated operation in the female 248 originated in the uterine app dages. Of these 151 were for suppurating conditions and for catarrhal or non-suppurative; the affections may classified as follows:—

Catarrhal salpingitis and ovaritis	60
Ovarian hæmatoma	11
Hydrosalpinx	26
Pyosalpinx	80
Pyosalpinx with ovarian abscess	17
Pyosalpinx with pelvic abscess	12
Ovarian abscess without pyosalpinx	14
Pelvic abscess originating in the uterine appendages	17
Tuberculous appendages	11
Total	248

ANATOMY.

The vagina and uterus, with the Fallopian tubes a ovaries, are contained, together with the bladder and part the rectum, in a potential space bounded by the peritone above and the pelvic fascia below, and continuous all rou with the subperitoneal connective-tissue space of the rest the abdominal wall. That part of this potential space wh is not occupied by the organs is filled up by the pel connective tissue, which is abundant about the supravagi cervix. From the cervix on either side radiate three co siderable collections of the connective tissue, the large forming the connective tissue at the base of the broad lig ment, otherwise called the cardinal ligament of the cerv the next most important collection, the utero-sacral lig ment, takes a curved course upwards and backwards towar the second piece of the sacrum, and the third runs forwa under the bladder towards the back of the pubes. Th ovary is covered not by peritoneum but by germinal epith lium, and may be considered as projecting through hole in the posterior layer of the broad ligament. Th vascular and lymphatic supplies of the ovary communicate freely through the hilum with those of the pelvic connective tissue. In the connective tissue run many important structures of which the chief for our present purpose are the arteries and veins and the lymphatic vessels. The ovarian artery, accompanied by the ovarian plexus of veins courses over the psoas muscle, through the ovario-pelvic ligament, along the upper part of the mesometrium to the side of the uterus, where the vessels very freely anastomose with the uterine artery and plexus of veins. The latter run inwards from the internal iliac vessels on the side of the pelvis, through the connective tissue at the base of the broad ligament, and turn upwards along the side of the uterus without entering its substance. The lymphatic vessels are also collected into two main plexuses, roughly corresponding to the veins. The ovarian lymphatics take the direction of the ovarian vessels upwards over the psoas and join some of the middle lumbar glands lying in close relation to the aorta and vena cava. The uterine plexus of lymphatics takes a similar course to that of the uterine veins and joins the lymphatic glands which are situated at the bifurcation of the common iliac and along the external iliac vessels. In their course from the uterus to the side of the pelvis the ovarian plexus and lymphatics receive communicating branches from those of the ovary and of the Fallopian tube. The ureters run from behind forwards and inwards through the cardinal ligament at the level of the isthmus and at a distance of about two-thirds of an inch laterally from the cervix. This relation is of importance, because sometimes cicatricial contraction of the pelvic connective tissue, the result of inflammation, compresses the ureter and gives rise to dilatation, hydronephrosis, and predisposition to suppuration of the kidney.

The relation of the organs to each other as seen from the peritoneal aspect is important from the practical point of view. The uterus with the broad ligaments stretch across the true pelvis from side to side, dividing the cavity into a shallow anterior fossa and a deep and complicated posterior one. The posterior fossa may be divided into three portions —one median and two lateral. The middle portion in its upper part is bounded in front by the uterus and behind by the front of the sacrum. The lower part forms Douglas's pouch and is marked off from the upper part by the utero-sacral ligaments; it extends downwards behind the upper part of the vagina and its posterior wall is formed by the rectum, which loses its peritoneal covering as it passes below the apex of the pouch. The lateral portion of the posterior pelvic fossa is placed at the side of the uterus above the utero-sacral fold and is bounded in front by the back of the broad ligament, to which the ovary is attached by the mesovarium. Over the ovary the Fallopian tube with the mesosalpinx is thrown like a cloak, the tube circling round so that its fimbriated extremity comes to lie below the lower end of the ovary a little above the level of the fold of Douglas.

The peritoneum is loosely connected to all the organs with the exception of part of the body of the uterus. With the anterior and posterior walls of the uterus as low down as the vesico-uterine pouch in front and as the insertion of the vagina behind the peritoneum is intimately connected, and immediately under it is situated the largest and closest plexus of the lymphatics of the uterine wall. This is a fact of great importance from the point of view of the spread of certain germs in puerperal infections.

PATHOLOGY.

Inflammation is the name given to the reaction of the tissues to the irritant effect of an injury, mechanical, thermal, chemical, or bacterial. In the pelvic organs inflammation is occasionally seen as the effect of mechanical or chemical irritants. Hæmorrhage into the peritoneum from tubal gestation sets up a surrounding and limiting adhesive peritonitis without the aid of micro-organisms; and a similar non-spreading simple peritonitis arises, for instance, in twisting of the pedicle of an ovarian tumour or of a pedunculated uterine fibroid. In certain cases so-called catarrhal inflammations of the tubes, as of other organs, are put down to supposititious causes which merely serve as a cloak for ignorance. Most of these cases probably depend on the action of germs, the mildness of the resulting changes being explained either by attenuation of the organisms or relative immunity on the part of the host. At any rate the so-called catarrhal cases shade imperceptibly into the purulent group, and it may be stated with confidence that severe and especially spreading inflammation depends upon bacterial causes; the tendency is constantly to trace more and more cases of all kinds of inflammation of the uterine adnexa as of other organs in the body to the action, recent or remote in time, of living germs. In recent cases living organisms can always be demonstrated by suitable methods, but after a certain time the germs tend to die; after they are dead their bodies disappear, so that the products of inflammation, even pus that has existed for a few months, are frequently sterile both in films and cultures.

For the present purpose the uterus and its appendages must be considered not as a collection of independent though continuous organs but as forming, together with the neighbouring peritoneum and pelvic connective tissue, a closely connected system, along the interior of which runs a canal leading directly from the surface of the body into the peritoneal cavity. In this canal are various narrowings, the external and internal os, the uterine orifices of the tubes, and their peritoneal openings. These afford very little resistance to the passage upwards of minute bodies and C. J. Bond has demonstrated that even inanimate particles quickly find their way from the vagina along the uterus and tubes into the peritoneal cavity, probably impelled upwards by mucous currents. In spite of this upward current, however, the upper part of the generative canal remains free from germs under ordinary conditions. In the lower part micro-organisms of many kinds normally live and thrive and among them are frequently found pathogenic germs, such as staphylococcus pyogenes albus and streptococcus pyogenes, probably in a state of diminished virulence. The upper boundary of the germ-containing portion is somewhere in the cervical canal; above this, in the epithelium and discharges of the body of the uterus, in the Fallopian tubes and the peritoneal cavity, no germs are found in the epithelium or secretions under normal conditions.

The body in a state of health is able to protect itself from invasion by germs and although these are the cause of certain affections, other suitable conditions must be present—that is to say, the organisms must be placed in favourable circumstances. Virulent cultures of pathogenic organisms such as the streptococcus pyogenes have been introduced into a healthy vagina and found to disappear in a very short time, while, as is well known, a similar introduction in other circumstances, as for instance, during parturition, may rapidly lead to the patient's death. Here as elsewhere not one agent, but a number of causes all converging towards the same point, are necessary for the production of disease.

It is necessary to distinguish between the time of implantation of pathogenic germs in the genital canal and that of their further spread either higher up the canal or into the tissues; a considerable period, amounting often to years, may intervene between these two occurrences. By far the most common opportunities for the introduction of virulent organisms are afforded by parturition and sexual intercourse. During the process of delivery, either at full term or in the earlier months of pregnancy, germs may be directly introduced, by the hands or fingers of the attendants, by septic instruments or appliances, or by dirty sponges, diapers, or articles of clothing. In sexual intercourse the gonococcus may be implanted, most commonly in the urethra and cervical canal. Much less frequently in these days of aseptic surgery infection takes place directly as the result of operations or of examinations carried out by dirty fingers or instruments. All these opportunities of infection occur practically without exception in women in the full vigour of adult life. In infants and young children the usual mode of infection by germs is direct inoculation by means of towels and clothes that have been defiled by specific discharge from other persons.

Among the conditions that favour the upward spread of organisms, already present or just implanted in the lower genital tract, are parturition and abortion. In pregnancy a great development of blood-vessels and lymphatics takes place in the uterus and its neighbouring organs and tissues, and the circulation of blood and lymph is extremely active both in this condition and for a time after delivery. At the placental site the mouths of large veins are plugged by blood clot. Bruises and lacerations of the tissues take place during the emptying of the uterus and afford a suitable nidus for the growth of germs; while the discharges, at first, unfavourable to such growth, soon appear to lose their protective properties. All these conditions are most favourable after delivery at term, but are present to a varying degree after abortion at any time. Menstruation also affords opportunities favourable to the extension of germs, more especially under certain conditions, such as over-exertion or exposure to cold. At this time the general resistance of the body is lowered, the patient feeling "unwell," and the menstrual discharges appear in certain circumstances to become altered in quality and suitable for the development of germs. Injuries produced by rough examination or by operations may lead to the spread or renewed activity of germs already present, as not uncommonly happens after forcible reduction of an adherent retroversion, or after curetting in the presence of a chronic salpingitis or pelvic peritonitis. The acute exanthemata also play a part in this respect, and it is probable that a certain number of cases of chronic pelvic inflammation in virgin adults may really have originated in an attack of scarlet fever or measles in childhood. Lawson Tait saw a number of cases of pelvic inflammation arising in small-pox in the Birmingham epidemic of 1872.

Puberty and the climateric also appear to have some influence. At the former epoch tuberculous affections of the generative organs not uncommonly occur, and at the latter inflammatory conditions of the organs that may have been dormant for years are apt to take on renewed activity.

When invasion or extension takes place the result depends, in the first place, upon the degree of virulence of the germs; instances have not been wanting where a virulent variety of germ, of streptococcus for instance, has created havoc in a number of obstetrical cases; even in such a series great individual variations are observed in the degree of injury inflicted upon different patients: many may die, others recover after a prolonged and painful struggle, and still others escape with comparative impunity. In the second place, the severity of the infection depends on the number of germs getting access to the body; this is only true to a certain extent, a relatively small number of virulent streptococci, for instance, being sometimes sufficient to cause death, while a large inoculation may only lead to a localised suppuration. The result depends, in the third place, on the resistance of the patient's tissues and blood fluids. This resistance is of extreme importance in determining the issue of the infection and must be invoked in explanation of the great variations in the severity of cases in the same epidemic. It is notorious that in certain conditions—such as chronic alcoholism, diabetes, chronic Bright's disease—the bodily resistance to invasion by the germs of wound and puerperal infection is greatly diminished; while the presence of a chronic inflammation, especially of a pus focus, forms a place of lessened resistance to the growth of septic and putrid organisms. Our knowledge of this part of the subject is, however, very limited, and convenient methods of observing and measuring the resistance of the body, local and general, are much to be desired.

The germs concerned spread further into the body along different routes, which depend to a considerable extent on peculiarities in the vital functions of the germs themselves. The best understood examples in this connexion are the two commonest causes of pelvic inflammation—the streptococcus, which tends to penetrate the tissues and spread along the lymphatics and blood-vessels; and the gonococcus, which tends to extend by continuity along certain surfaces. Let us first briefly consider the sequence of events that follows on streptococcus invasion.

Invasion by streptococcus pyogenes.—In the case of puerperal infection by the streptococcus the germ multiplies first in the fluids and on the surface of the endometrium, whence in some cases it penetrates into the uterine wall, either at the placental site or over the whole surface of the endometrium. In other instances invasion takes place by way of a laceration of the vagina, cervix, or other part of the genital canal. In the most severe and fatal cases the spread is first along the lymphatic spaces, by which it easily penetrates the thickness of the uterine wall until it attains the close and abundant plexus of lymphatic vessels immediately under the peritoneal covering of the organ. Through the serous membrane the streptococcus passes into the peritoneal cavity where it sets up a varying degree of peritonitis; if the patient survives the infection may invade the ovary from its peritoneal surface, giving rise to different varieties of ovaritis, follicular and interstitial; the Fallopian tube is invaded through its open peritoneal end, and may be closed as a consequence of peritonitis, the fimbriæ being plastered down on to some neighbouring surface.

In other cases the streptococcus spreads along the lymph vessels in the uterine wall into the ovarian or uterine plexus of lymphatics and gives origin to a lymphangitis. Where the spread takes place along the ovarian lymphatic plexus the resulting inflammation may extend widely in the posterior part of the iliac fossa and up the back of the abdomen, irritating and setting up inflammation in the lumbar lymphatic glands at the level of the lower ends of the kidneys; where the uterine lymphatics are invaded the inflammation extends outwards between the layers of the broad ligament to the side of the pelvis, the iliac glands being implicated, especially those at the bifurcation of the common iliac and along the external iliac vessels. A further result of extension along the ovarian plexus may be the spread of inflammation into the hilum of the ovary along the communicating ovarian lymphatics, and it is even possible that in rare instances the Fallopian tube may become similarly infected. Lewers, at the Obstetrical Society in 1888, showed a specimen taken from a patient who died ten days after labour, in which inflammation had arisen between the layers of the right broad ligament and had spread into the ovary causing fibrinous adhesions and a small abscess.

In other cases, usually less rapid and certain in their course, the streptococcus invades the large veins which, filled with blood clot, are present in considerable numbers at the placental site. The invasion causes an extension of clotting into the communicating veins, and this thrombosis may be limited to the walls of the uterus itself or may spread along the uterine or ovarian veins between the layers of the broad ligaments. The thrombosis may thus extend along the ovarian veins as far as the inferior vena cava or the renal veins or along the uterine into the internal iliac vein and so into the common iliac and inferior cava. As a result portions of breaking-down blood clot may be carried to the lungs or to the other organs and tissues of the body, giving rise to pyæmia.

When the streptococcus spreads along the lymphatics or the veins the neighbouring cellular tissue participates more or less widely in the resulting inflammation. Thus the organism may give rise to peritonitis or to cellulitis but neither affection is, as a rule, pure, peritonitis being always accompanied by some degree of inflammation in the subperitoneal connective tissue, and cellulitis being generally accompanied by more or less exudation or adhesion in the overlying peritoneum. In some cases, apparently not very common, the streptococcus appears to spread, like the gonococcus, by continuity along the mucous surfaces.

Invasion by the gonococcus.—The gonococcus appears to be capable in some cases of penetrating deeply into the tissues or invading the blood-vessels or lymphatics, like the streptococcus, but its usual course is along the surface of the mucous membrane, giving rise to inflammation of very varying severity. In the body of the uterus it gives rise to endometritis, which may be glandular or interstitial or both. In the tube it causes endosalpingitis, which may not pass beyond the serous stage or may result in the production of copious pus; the muscular and peritoneal coats of the tube are involved in degree varying with the severity of the infection; they may swell and elongate so as to extend over the fimbriæ, which thus become folded in the lumen of the tube. The tube thus becomes closed in consequence of the inflammation of its walls—salpingitic closure. In the peritoneum the gonococcus sets up inflammation which is usually localised and may or may not be attended by the formation of pus. As a consequence peritonitic closure of the tube may take place.

Other germs.—Besides the streptococcus pyogenes and the gonococcus many other germs give rise to inflammation of the female pelvic organs, alone or in combination. Among the commonest are the staphylococcus pyogenes aureus and albus, the pneumococcus, and the bacillus aerogenes capsulatus. The bacterium coli commune is apt to spread rapidly through the tissues after the death of a patient so as to prevent the discovery at post-mortem examination of the organism that caused the fatal inflammation. It is, however, a frequent cause of infection during life; in the puerperium it is often found in symbiosis with the streptococcus and appears to render the prognosis graver. At other times it invades chronically inflamed organs from adherent intestine and it appears to be a not uncommon source of secondary infection of old tuberculous appendages.

THE REACTION OF THE TISSUES TO INVASION BY GERMS.

So far we have been devoting our attention to the doings of the invading germs. Let us now turn our attention to the efforts that are made by the body to overcome the invasion. First, we have to remember that the infection is not a merely particulate one, but that the germs as a result of their vital biochemical processes, may act upon the tissues, and especially the fluids of the host, in at least three ways: (1) by withdrawing material for food; (2) by excreting substances that are useless or that have been partially used for food; and (3) by the manufacture of bodies definitely intended to be poisonous to the host. In some or all of these ways a toxic effect is exerted at first in the immediate vicinity of the germs, where the circulation becomes hurried in vessels which are first contracted but quickly become dilated. Soon the circulation becomes slower, until stasis occurs. As these changes proceed exudation takes place first of inflammatory lymph and then of leucocytes with a number of red corpuscles varying with the severity of the infection. The effusion of lymph gives rise in the solid tissues to a soft boggy swelling known as inflammatory œdema. Soon the lymph coagulates, fluid serum draining away in large quantities through the lymphatics and carrying with it toxins into the circulation, while a solid fibrinous network is deposited in the tissues giving rise to brawny hardness. When lymph is exuded into the peritoneal cavity the same clotting takes place, fibrin being deposited on the surface of the serous membrane and in the subperitoneal tissues, while the serum either at once drains away or collects in pockets bounded by adhesions of the adjacent viscera or by delicate transparent lamellæ of lymph; in this way an elastic or fluctuating tender swelling is formed.

The exudation of sero-fibrinous material forms the first line of defence against the invading germs. At the same time as it is forming the absorption of toxins from the marauders acts as a powerful message to the phagocytes, paralysing them in the worst cases so that they keep their distance; in other cases stimulating them to hurry in crowds to the field of danger. This effect of the invasion of germs is known as chemiotaxis, negative in the former grave cases, positive in the latter and more hopeful.

As phagocytes act the endothelial cells lining the capillary vessels and lymphatics, and the polymorphonuclear leucocytes which escape from the blood-vessels, and which in inflammation are produced in increasing numbers, chiefly by the bone marrow. At the scene of conflict the phagocytes collect in varying numbers, forming masses distributed at intervals along the vessels and through the tissues, and in some instances thick strata mixed with fibrinous coagulum on the invaded surface. The phagocytes take up and destroy the invading germs, or the germs penetrate and grow in them and ultimately cause their death. As the fight goes on a third barrier is erected by the formation of a layer of granulation tissue either on the injured surface or round the collections of dead leucocytes, necrotic tissue, and weakened or dead micro-organisms that result from the conflict.

The absorption into the circulation of poisons from the living organisms or from their dead bodies, together with the response made by the blood and tissues in the formation of antibodies of many kinds, gives rise to the most profound and varied effects on every organ and function of the body. The circulation is hurried; the pulse is more frequent and often at first bounding but soon becomes small and soft, until finally it may cease to be felt at the wrist; the blood is altered, the leucocytes being increased in number, while the red corpuscles diminish in number and quality and often alter in shape; the temperature of the body is usually raised but in the worst cases becomes subnormal and remains so until death ensues. The nervous system suffers, sleeplessness and delirium become common, and the whole neuromuscular tone of the body becomes profoundly altered, as shown by the powerlessness of the patient and the aspect of grave illness in the altered features. The gastro-intestinal, the hepatic and renal organs partake with the rest of the body in the widespread disturbances of function and structure.

The host may succumb or may be able at any point to put an end to further invasion. In the worst forms of puerperal infection death may result in from 24 to 48 hours; in such cases no inflammatory reaction may be observed; the walls of the uterus at the seat of invasion contain large numbers of germs, usually streptococci; and a few ounces of serum, generally blood-stained, are present in the peritoneal cavity and teem with the germs. In mild cases a moderate amount of sero fibrinous exudation with few leucocytes may suffice to put an end to the invasion; or there may be a considerable fibrinous or fibrino-purulent effusion, as happens more especially in pneumococcal, gonococcal, and tuberculous infections. In other cases pus forms, often in large quantities, and may drain away from the producing surface or may be retained in irregular collections in the tissues or in hollow organs. In still other cases, especially in infections by the bacterium coli or by certain varieties of saprophytic germs, considerable destruction of the tissues takes place, giving rise to sloughs or gangrene, and to the formation in the organs, peritoneal cavity, or cellular tissue, of collections of stinking, discoloured, blood-stained putridity.

When the fight is over the injuries remain to be repaired and the débris to be removed from the field of battle. The repair and removal may be complete but are often incomplete, or take months or years for their accomplishment. Repair takes place by means of newly formed fibrous tissue and epithelium. Serous exudations are usually absorbed but in certain circumstances may remain for many years or gradually increase, as in the case of hydrosalpinx and of certain ovarian cysts resulting from perioöphoritis. Fibrinous deposits become absorbed, being replaced by fibrous adhesions which, in connexion with the more moveable abdominal organs, often become absorbed to a remarkable extent; in the neighbourhood of the less moveable uterus and appendages absorption appears to be less notable. Small collections of dead leucocytes and fibrin in the tissues undergo fatty degeneration and become absorbed. A larger collection of pus may continue to act as an irritant and keep up surrounding inflammation until it reaches a surface and makes its escape. Or such a collection may remain quiet sometimes for many years; in this case the locality of the pus is always a place of lowered resistance, and it is liable on slight causes—as the result of cold, of a blow, of a fall, or of over-exertion—to break out into renewed activity. In other cases a collection of old pus gives rise to a condition of general ill health, presumably by the long-continued absorption of small doses of toxin; in this way a condition of chronic neurasthenia may result or, as happens in some cases of old-standing pyosalpinx, the patient becomes prematurely aged, haggard, and worn-looking, and finally wastes and dies from exhaustion or as the result of a terminal infection.

CLASSIFICATION.

The most desirable classification of pelvic inflammations would be according to the germ which is present. In very many cases, however, it is not possible to make certain of the causative germ, more especially in the chronic cases, in which the microbes have died out and left no distinctive trace of their action, as in many cases of puerperal and gonorrhœal salpingitis. Moreover, the same germ may give rise in different patients, or in combinations in the same patient, to every degree of inflammation, serous, fibrinous, or purulent. From the clinical point of view it is customary and convenient to divide the cases into catarrhal or non-suppurative and suppurative, the latter including all cases where an amount of pus has been formed sufficient for detection by the unaided sight. In the catarrhal group are included many cases that really depend on invasion by known pathogenic organisms. This statement is based on the fact that the two groups shade imperceptibly into each other; on a comparison of the appendages in many so-called catarrhal cases with those of the less affected side in cases of suppuration; and on a consideration of the infinite variety in degree and extent of inflammations known to be caused by the same germ.

The non-suppurative group includes hydrosalpinx and a heterogeneous and not entirely satisfactory collection of cases of catarrhal salpingo-ovaritis. Among the catarrhal cases in my list are 42 in which salpingitis was the leading feature. The tubes presented all degrees of alterations: in some there were congestion and œdema of all the coats, usually with a small amount of accompanying pelvic peritonitis; in others great thickening and induration of the muscular and peritoneal coats with marked peritonitic changes; in others, again, there were universal adhesions to the surrounding structures with or without closure of the peritoneal ostium, but without distension of the lumen; and finally in two cases the process had resulted in atrophy, the tube and ovary forming a small, densely adherent, puckered mass, with shrunken broad ligament. The affection was bilateral in about two-thirds of the cases. Catarrhal salpingitis appears to favour the occurrence of tubal gestation, in many cases of which more or less extensive old fibrous adhesions are observed about the pelvic peritoneum and appendages of the pregnant or opposite side; in a considerable proportion of the cases the tube on the opposite side to the pregnancy is converted into a hydrosalpinx. A second group included 18 cases in which various changes in the ovary were the salient features.

Corpus luteum cysts	6
Graafian cysts	3
Small cystic ovaries	4
Widespread adhesions of ovaries	5
Total	18

In this group the affection was bilateral in four and unilateral in 14. The Fallopian tubes showed evidence of catarrh in a few and were adherent in several more cases. In two of the cystic ovaries there were no adhesions near the fimbriated extremity, but firm old membranes bound the middle of the tube to the ovary and back of the broad ligament. In one of these the patient was just recovering from the fifth attack of acute pelvic peritonitis that had occurred in three and a half years, and in the other chronic illness and neurasthenia had existed for three years, in both patients since the last labour. The frequent coexistence of small Graafian and corpus luteum cysts with adhesions and other signs of old inflammation of the Fallopian tubes and pelvic peritoneum suggests a causal connexion between the two conditions, so that it seems preferable to include many of these small cysts with inflammations of the appendages rather than with neoplastic formations.

The Fallopian tube may become closed at its fimbriated extremity either as a consequence of salpingitis, the inflammatory swelling of the muscular and peritoneal coats extending over and invaginating the fimbriæ, or as a consequence of pelvic peritonitis, the fimbriæ becoming plastered down on to the ovary or other neighbouring surface. It is frequently impossible to decide by which of these methods a particular tube has become closed. In 73 instances where this was possible salpingitis had been the cause of the occlusion in 41 and peritonitis in 32. The two tubes of the same patient are not infrequently closed by different methods, one by salpingitis and the other by peritonitis. When the peritoneal ostium has become closed a tube may remain empty or may become the seat of a collection of fluids of different kinds, serum, pus, or blood.

Hydrosalpinx.—An occluded tube containing serous or watery fluid in greater amount than a drachm or two is called a hydrosalpinx. The amount of fluid varies from a few drachms to two or three pints and the shape of the resulting tumour varies according to the amount of distension, being usually club- or retort-shaped in small and moderate-sized cases and banana-shaped or globular in the larger ones. The fluid contained in the smaller varieties is serous and in the larger becomes thinner and more watery. No germs are present in film or culture. In some cases there are few or no adhesions, but, as a rule, fibrous adhesions about the original site of the peritoneal ostium bind this part of the sac firmly to the surface of the ovary, the back of the broad ligament, and the side and floor of the pelvis. Hydrosalpinx appears in its origin to be a result of catarrhal salpingitis and pelvic peritonitis, but when of long duration acquires the characters of a retention cyst. In five cases of double hydrosalpinx in which the accumulation of fluid amounted to eight or ten ounces or more the time taken in the accumulation had extended over many years, one containing three pints of fluid having probably existed for 18 years. A large proportion of my cases of hydrosalpinx have been found in operations undertaken for other conditions. In tubal pregnancy the tube on the opposite side is often converted into a hydrosalpinx (nine in 62 cases); hydrosalpinx was also found in association with uterine fibroids (six cases), with large fibroma of the ovary, and in a few cases with large ovarian cysts; it was also found with prolapse of the uterus in two cases and with pyosalpinx on the opposite side (five out of 109). Certain accidents are occasionally observed in connexion with hydrosalpinx. Axial rotation has occurred many times, and hæmorrhage into the contained fluid is not uncommon, especially in connexion with tubal pregnancy on the opposite side. As a rare occurrence the fluid escapes through the uterus in gushes from time to time—intermittent hydrosalpinx.

Pyosalpinx.—Pyosalpinx is the name given to a Fallopian tube closed at its peritoneal opening and containing pus. The condition usually arises as a consequence of inflammation spreading from the uterus directly into the tube, but may sometimes arise in peritonitis by extension of inflammation through the peritoneal ostium, as is frequently observed in tubercle and sometimes in puerperal cases. Occasionally pyosalpinx on one side co-exists with hydrosalpinx on the other. A pyosalpinx usually forms an extensively adherent thick-walled hard tumour, but occasionally (eight cases in 109) is less adherent and contains a large collection of pus in a relatively thin-walled cavity, thus to some extent resembling hydrosalpinx. The amount of adhesion varies greatly in different cases, but the omentum and some coils of small and large intestine are usually involved, in addition to the denser and more extensive adhesions to the ovary, back of the broad ligament, uterus, and floor of the pelvis. Among my cases, pyosalpinx was bilateral in 55 and unilateral with normal appendages on the opposite side in only 18.

Pyosalpinx.—

Bilateral in	55
With hydrosalpinx on opposite side	5
With salpingitis	20
Opposite appendages not noted	11
Opposite appendages normal	18
Total	109

Pyosalpinx is frequently complicated by ovarian abscess (17 in 109) and somewhat less frequently by collections of free pus in the peritoneal cavity (12 in 109). The contained pus is found to be sterile in a large proportion, usually more than half the cases. In 13 of those included in my list pus was sterile in four, saprophytes or bacterium coli were present in five, and streptococcus, staphylococcus, staphylococcus and pneumococcus, and the gonococcus in one each.

The following was the result of bacteriological examination:—

Bacteriology of Pyosalpinx.

Sterile	4
Streptococcus	1
Staphylococcus albus	1
Staphylococcus and pneumococcus	1
Gonococcus	1
Saprophytes	5
Total	13

In addition to abscess of the ovary and intraperitoneal abscess many other complications occur in cases of pyosalpinx. Hæmorrhage into the contained pus is not infrequent and ovarian hæmorrhages are common. Rupture of a pyosalpinx not rarely happens as the result of straining or over-exertion, as, for instance, in lifting weights. In other instances rupture occurs as the result of rough examinations or manipulations, as, for instance, in the forcible reduction of a retroverted uterus or during the enucleation of a submucous fibroid. Rarely axial rotation of a pyosalpinx has been observed. Sometimes cicatricial contraction of the tissues at the base of a pyosalpinx leads to compression of the ureter with its consequences, dilatation and hydronephrosis, and tendency to suppuration of the kidney. In association with tubal gestation on the opposite side pyosalpinx is occasionally found. I have myself operated on one such case and have assisted in two others, one complicated by tubo-ovarian abscess and the other by an acute gonorrhœal salpingitis. Complications on the side of the uterus are very common, more particularly in the form of chronic metritis and endometritis, the remains in many cases of the original infection from which the tube became secondarily infected. Displacements of the uterus are also common and prolapse was present in four of my cases. Fibroids are not uncommonly associated with pyosalpinx, which adds a grave risk to the operation of hysterectomy.

Pyosalpinx is less frequently seen in cases of carcinoma of the cervix. Pregnancy may supervene in a patient with pyosalpinx on one side, as happened in one of my cases, where rupture of the pyosalpinx and fatal peritonitis occurred at the sixth month.

Ovarian suppuration.—Abscess of the ovary may arise in a corpus luteum or in a Graafian follicle, or suppuration may be disseminated irregularly through the stroma of the organ. The exciting micro-organisms reach the ovary in at least two ways: the peritoneal surface may be infected by pus escaping from the open end of the Fallopian tube or forming in the pelvic peritoneum, or pyogenic organisms may extend outwards through the wall of the uterus and along the lymphatics to gain an entrance through the hilum of the ovary. The relation of the Fallopian tube to the suppurating ovary in my cases shows that, at any rate in the subacute and chronic cases, by far the most frequent route of infection is by way of the tube.

When infection takes place from the peritoneal surface a corpus luteum is most frequently the seat of suppuration. In all my cases of suppurating ovary, with one exception, the patient was parous, the interval between the last pregnancy and the date of operation varying from three months to 31 years. In 12 of the total number of ovarian abscess cases operation was undertaken in eight months or less after parturition. Of seven cases in which a bacteriological examination was made, in four the pus was found to be sterile, while in the other three it contained streptococcus, gonococcus, and staphylococcus pyogenes aureus, each in one case.

Excluding from consideration suppuration of large ovarian cysts, I have operated in 31 cases of suppuration of the ovary, including one case of tuberculous suppuration of a solitary ovarian cyst of the size of a duck's egg. In 18 of the remaining 30 cases suppuration had taken place in a corpus luteum and in 12 apparently in Graafian follicles, the abscess in these cases being solitary in nine and multiple in three. In one of the 30 cases the ovary was removed through a posterior vaginal incision and the Fallopian tube was ascertained at a subsequent abdominal section to be inflamed and densely adherent at its outer end. In the whole of the rest of the cases the Fallopian tube showed signs of inflammation, pyosalpinx being present in 17, while in the other 12 the tubes were inflamed without the production of obvious pus In another case not included in this group the process of labour caused rupture of a moderate-sized dermoid ovarian cyst on the right side and at the same time rupture of an old pyosalpinx on the left side. The patient was admitted in a desperate state of septic peritonitis and died after operation from perforation of the sigmoid flexure where this had been adherent to the pyosalpinx.

Tuberculous salpingitis.—The tubercle bacillus rarely gains access to the Fallopian tube and pelvic peritoneum by way of the uterus and vagina. The usual routes are by way of the peritoneum or through the blood stream. The germs may be absorbed from the digestive or respiratory tracts and lodge in the bronchial, mediastinal, or mesenteric glands, whence at a later period they may be carried to distant organs and among others to the Fallopian tube or ovary. From the peritoneal cavity the tubes are frequently secondarily infected. Commonly enough miliary tubercles are seen scattered over the peritoneal covering of the tubes and broad ligaments, and fluid exudations in the peritoneal cavity convey germs through the open ostia of the tubes. Tuberculous peritonitis in the female is associated with salpingitis in 50 per cent. of the cases, and in most of these the tube is affected secondarily from the peritoneum. The genital tract may also be invaded by extension from other tuberculous organs, as, for instance, from the cæcum, rectum, or base of the bladder. When the generative organs are affected by tubercle the seat of the disease is by far most frequent in the Fallopian tubes (90 per cent.), and this appears to be due to the direct communication between the interior of the tube and the peritoneal cavity. Where the uterus is tuberculous, in the majority of cases the infection proceeds from the tubes by direct extension.

Of 20 patients operated upon by me for tuberculous peritonitis, in 11 it was ascertained that the Fallopian tubes were affected, in several of them the ovary also taking part in the disease. In three cases as observed after removal of the uterus the endometrium was extensively involved.

Hæmorrhages in connexion with salpingitis.—Effusions of blood are frequently observed in connexion with chronic inflammations of the uterine appendages. In hydrosalpinx, especially when it coexists with pregnancy of the opposite tube, the fluid is usually found more or less deeply tinged with blood. In pyosalpinx, also, hæmorrhage may take place into the wall or contents (four cases), or may be found in the corresponding ovary (21 in 109 cases). The most frequent situation of the ovarian hæmorrhage in these cases is in connexion with the follicles, which are often seen surrounded by a red border one-sixteenth of an inch or so in thickness, due to hæmorrhage in the tunica interna. The contents of such follicles may be clear, but more frequently consist of clotted blood. Less frequently hæmorrhage occurs in connexion with corpora lutea either in the interior or, as sometimes happens, forming a broad band round the periphery. Irregular interstitial hæmorrhages are less common. Similar ovarian hæmorrhages occur, but less often, in connexion with non-suppurative affections of the tubes; they were present in five out of 41 cases of catarrhal salpingitis. Occasionally as the result of severe salpingitis hæmorrhage may be more extensive and escape into the peritoneal cavity to form a hæmatocele. Such cases appear to be far from common and great care has to be taken to exclude the possibility that a tubal gestation has been the cause of the condition. I have only seen two cases of pelvic hæmatocele in which a careful examination made it highly probable that the originating cause was salpingitis. In one of these a married sterile patient, aged 39 years, had been losing flesh for 12 months and was just recovering from her third attack of pelvic peritonitis. There were marked catarrhal salpingitis on both sides and recent acute pelvic peritonitis. The other case occurred in a patient, aged 28 years, also sterile, who had had repeated attacks of inflammation for two years, and whose right tube was closed by peritonitic adhesions in which there were yellowish caseous collections, probably tuberculous.

Hæmatoma of the ovary.—In 11 other cases grouped as inflammatory, I have seen hæmatoma of small and moderate size in the ovary of both sides in five and of one side in six. All the patients complained of severe and long-continued pains, most of them with acute exacerbations resembling attacks of pelvic peritonitis. In five of the cases the ovaries were densely adherent, although in two out of the five the tube was free and apparently normal. In two other cases, making four in all, the tubes appeared to be normal, and in the other seven the tubes were either catarrhal or adherent; in one case there was recent acute pelvic peritonitis. In all the 11 cases the blood cyst in the ovary appeared to be the main cause of the patient's illness. The class of patient in whom ovarian hæmatomata were observed differed markedly from those in whom the other forms of inflammation are observed, in that four of them were single and five were married nulliparæ; the other two patients had each borne one child, one nine and the other 22 years before operation; the age of the patients varied from 19 to 39 years. Three of the five married nulliparæ were probably gonorrhœal.

BACTERIOLOGY.

In 12 recent puerperal infections micro-organisms were found in every case, the streptococcus being present in ten, in four in pure culture and in the other six in association with staphylococcus pyogenes aureus and other varieties of germs. In 43 cases of subacute and chronic suppurative pelvic inflammations no germs were present on films or culture in ten. Streptococcus grew in pure culture in ten, and in association with other germs in five. In 13 cases various forms of saprophytes were found, and in the remaining cases staphylococcus aureus and albus, pneumococcus and bacterium coli commune were observed.

INCIDENCE.

The age of the patients varied from 17 to 54 years. Only seven were 20 years or less and of them three had tuberculous appendages, two had inflammations originating in childbed, and one gonorrhœa, while in the seventh case, in a girl, aged 18 years, a fœtid intraperitoneal abscess of considerable extent and obscure origin suddenly made its appearance and rapidly increased; rapid recovery followed upon a posterior vaginal incision and the diagnosis therefore remained pelvic abscess simply. 11 of the patients were 46 years of age and upwards and of these five were 50 years or more; in each of the five a suppurative condition had probably existed for from 11 to 31 years and had then given rise to acute symptoms demanding operation. All the other 242 patients, more than 93 per cent., were between 21 and 45 years old—that is to say, at the age when they should have been at their best as active and useful members of society.

Among the 260 cases suffering from pelvic inflammations were 29 single and nulliparous patients. Such patients suffer from tuberculous affections with much greater relative frequency than parous women; of 13 patients with tuberculous affections, including one of hydrosalpinx and one with tuberculous suppurating ovary, nine were single and two more sterile. Among the patients suffering with ovarian hæmatoma single and sterile women also formed the great majority; of 11 such patients four were single and five married but nulliparous women. In the other groups of cases single women are relatively much less frequently found. Of 109 cases of pyosalpinx only eight occurred in single women; of the eight, four were probably gonorrhœal and two were due to secondary infection by saprophytes of old tuberculous appendages. The origin of the pyosalpinx in the other two was obscure. Of 29 patients with intra-peritoneal pelvic abscess five were single and nulliparous; in one of these the abscess was due to suppurating silk ligatures remaining after a laparotomy performed elsewhere, one was due to suppuration of a hæmatocele two years after supravaginal hysterectomy had been performed elsewhere, and the cause of the other three was not satisfactorily made out. 21 out of 97 patients suffering with non-suppurating inflammations and 34 out of 163 with suppurating conditions were sterile married women. Satisfactory clinical evidence of gonorrhœa was obtained in 48 cases. In two of the non-suppurative cases and seven of pyosalpinx the patients were syphilitic.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Mr. J. Dundon, F.R.C.S. Eng., and Mr. L. G. Gunn, F.R.C.S. Irel., have been elected additional examiners in surgery.

NEW CONVALESCENT HOMES.—A convalescent home scheme has long been the desire of the friends of the Manchester and Salford Hospital Saturday Fund and at length it is in operation. There is a temporary home for women at Arnside on Morecambe Bay and the first inmates were received some weeks ago. At present there is accommodation for 30 patients, but the house can, if necessary, be much enlarged. The men's home, Plas Mariender, at Penmaenmawr, was opened towards the end of May. Here there is accommodation for between 30 and 40 men, but extensions are contemplated in the future. Both at Arnside and Penmaenmawr the patients have given warm expression to their appreciation of the comforts of their pleasant homes.

The Harben Lectures
ON
EXPERIMENTAL RESEARCHES ON SPECIFIC THERAPEUTICS.

Delivered at 20, Hanover-square, London, under the auspices of the Royal Institute of Public Health,

BY PROFESSOR PAUL EHRLICH, M.D.,
DIRECTOR OF THE KÖNIGLICHES INSTITUT FÜR EXPERIMENTELLE THERAPIE, FRANKFORT.

LECTURE I.

Delivered on June 5th.

IMMUNITY WITH ESPECIAL REFERENCE TO THE RELATIONS EXISTING BETWEEN THE DISTRIBUTION AND ACTION OF ANTIGENS.

GENTLEMEN,—There can be no doubt that the three great fields of knowledge—pharmacology, toxicology, and therapeutics—in their theoretical and practical aspects form the most important branches of medicine. Pharmacology has but just emerged from the stage of pure observation and description. One was content formerly with describing the physiological effects and the secondary action of substances which act pharmaco-dynamically and the changes which they bring about in the organs and tissues of the body from the morphological standpoint. It is to the great influence which chemistry exerted on medical science that we owe a change in this state of affairs. It was about the middle of the last century that the influence made itself specially felt. But therapeutics were chiefly symptomatic, and so it is in many cases to-day. The features of an etiological treatment, directed against the causes and the seat of disease, were not satisfactorily brought out by merely insisting on the relationship which existed between the constitution of drugs and their action; the fact was overlooked that between chemical constitution and pharmacological action another and important bond of union exists which influences the relations between the pharmaco-dynamic agent and the substance on which it is intended to act. This bond of union is the mode of distribution and represents the sum of the peculiarities of the cells and tissues and of the drug.

I may mention that from the beginning, as the result of my studies on dyes, I have endeavoured to point out the necessity of the study of localisation—in a word, to give pharmacology an etiological and therapeutic tendency. Great must be our admiration for the powers of nature, in view of the fact that the living organism, when it takes upon itself the production of curative agents, does this in such a manner that they form ideal etiological remedies.

The protective substances of the blood, regarding which I shall speak to-day, completely fulfil the requirements of the case, and the study of antigens and antibodies may form the basis of the relationships which must exist between constitution, distribution, and action in order that our treatment may be successful. The discovery of antitoxins by von Behring, fundamental in itself, opened to pharmacology and therapeutics this new field: antitoxins and antibacterial substances strike only those objects for whose destruction they have been produced by the organism. I call these substances monotropic; the monotropism of these antibodies is characterised by the fact that they are bacteriotropic or etiotropic in general—i.e., they are directed against bacteria or against those products of their metabolism (toxins) which cause disease. The definition of monotropism is, therefore, here overlapped by that of specificity which, in the language of the study of immunity, characterises monotropic action. As the cause of this specificity we must note, in my opinion, only the effect of chemical relations which exist between the agents of infection or their products and the antibodies.

From the very beginning my standpoint has been that all those substances which have the power to bring about the creation of antibodies, I mean the antigens, must be entirely separated from the other pharmaco-dynamical and poisonous substances as a matter of principle. That difference I consider to be of the greatest importance, and this is further borne out by the fact that in spite of the most strenuous endeavours we have been unable to find any antigen of a known chemical constitution. I believe that in the absorption of antigen-like substances by the body we have a phenomenon which bears a close resemblance to the assimilation of nutritive substances. In the case of the other poisonous substances we have more simple phenomena as causes of localisation, but, in my opinion, the powers which influence the distribution of toxins and kindred substances belong to the domain of chemical synthesis. It seems to me that the ever-increasing endeavour tó build causal relationships on the ground of purely formal analogies is but *little fitted to advance our knowledge.* The condition therefore necessary for reaction is the presence of two groups, whose chemical relationship is of the closest and whose interaction is therefore the condition of their union. This axiom as to union is the basis of my side-chain theory.

Let us consider in the first place the action of comparatively simple toxins, which differ in the phenomena of *intoxication to which they give rise*; the action of the diphtheria toxin, for example, is absolutely different from that of the tetanus toxin. I designate that group of the toxin molecule which is the cause of its peculiar poisonous action as its toxophoric group, but the presence *of this toxophoric group is not of itself* sufficient to bring about the poisonous action, for whilst the guinea-pig is exceedingly sensitive to the tetanus toxin the rabbit possesses a relative immunity. The *cause of such difference we must* therefore attribute to the distribution or localisation of the *toxin.* When the poison and the sensitive organs do not come in contact or when the latter are not present, the action remains absent. If we assume those peculiarities of the toxins which cause their distribution to be localised in a special group of the toxin molecule and the power of the organs and tissues to react with the toxin to be localised in special atom groups of the protoplasm, we arrive at the basis of my side-chain theory.

The *distributive group of the toxins I call the* "haptophoric group," and the corresponding chemical organs of the protoplasms the "receptors." The relations between the receptors and the haptophoric *groups represent the* conditions under which distribution takes place. The toxic action can occur only *when there are* present receptors fitted to anchor the toxins. In order *that the* poisonous action may take place, we must postulate not only the presence of *receptors, but that they should* be present in positions favourable to the toxic action being brought about. When *both the receptors* and the *organs* sensitive to the action of the poison are *present,* the conditions *for infection* are naturally most *favourable*; then distribution takes place at *once,* the poison circulating until it reaches the sensitive cell. The localisation of the receptors is, then, of great moment *for the distribution* of toxin in the organism, and *consequently* for its sensitiveness to poisonous action. One may therefore, in general, distinguish four *different* types of *distribution*: 1. In which the receptors are not present, the animal possessing natural immunity (the *formation of* antibodies cannot take place). 2. In which receptors are present, but only in those organs *on which the* poison does not act, or in organs of lesser importance; *here,* again, the animal *possesses* natural immunity (antibodies may be formed, and immunisation is easily carried out). 3. *In which the* receptors are distributed over various parts of the organism, and are present in the organs which are sensitive to the action of the poison. Here a relative immunity is present, and infection depends chiefly upon the manner in which the poison is introduced (the conditions for *antibody formation* are present and those for immunisation are *more* or less favourable). 4. In which the *receptors* are present only in the organs which are sensitive to the poison; in this class the organism is exceedingly sensitive to the poison (antibody formation is possible, but immunisation is difficult to carry out and must be begun with small doses or with weakened poisons).

I think that this *systematic* division clearly shows the possibilities of distribution and localisation as well as the conditions under *which* a poisonous action can take place and what *must be* the aim of antitoxic treatment—viz., the alteration of the natural conditions of distribution and interference with the action of the poison. In my view, which is based on extensive experience in experimental research, the *antitoxins* are purely and simply receptors fitted for union with the poisons which have entered the circulation.

I have *always held* the view that the antitoxins do not in any way destroy the toxin, but that they merely limit its *sphere of action* by their union with it. When we speak of monotropism or specificity in the case of antigens and antibodies, we of course mean only the chemical relations between haptophoric groups and receptors. For example, toxins may be specific and yet act upon the cells of all species of animals if the toxin-anchoring receptors be widespread amongst them. The other extreme we find in those cases in which the organism itself reacts to elements introduced into it and forms substances, antibodies, which act on the corresponding antigens; we have here to do with antibodies which are specifically monotropic, just as the antitoxins are, and which affect only those substances *to which they owe their* origin. The only difference is that the antitoxins act by localisation alone; when they have anchored the toxins their work is done. The other antibodies act, it is *true, at first* in a similar way on the substances sensitive to them; but they have a further action on the anchored substances, an action which is either direct, as in those cases (agglutinins and precipitins) in which, like the toxins, they have *special ergophoric* groups, or indirect in that the union is merely preliminary to their further action on their prey. Thus one class of these antibodies has the power of rendering the *cells assimilable* by phagocytes (opsonins, bacteriotropic substances); *another class* (amboceptors) *has* the power of rendering the cells liable to the action of toxin-like constituents of the blood serum (complements). In the latter case by the simultaneous *action of two substances a destructive* effect is produced. These substances are also called cytotoxins. They are of special importance in considering the question of the relations between *constitution, distribution,* and action, because the differentiation between haptophoric and *toxophoric groups exists in their case,* distribution and toxic effect being dependent upon two different substances, the more stable amboceptor controlling the distribution, and the labile complement the toxic effect. The complement has no direct relations with the cell, on which it *acts through* the medium of the amboceptor. It is a normal constituent of the blood *serum* the concentration of which undergoes no change as a result of the *process of immunisation. On the other hand,* the amboceptor is a new formation brought about by immunisation, and, on the ground of the principle already admitted, it must *appear* probable that the amboceptor, like the antitoxins, possesses a marked monotropism for the corresponding antigen. It is the amboceptor alone that stands in direct relation to the cell and is quantitatively anchored by it. This anchoring of the amboceptor takes place with a maximum of chemical energy—it occurs even at 0° C. The union of the amboceptor and the cell has no harmful results on the latter. On the other hand, the *amboceptor-laden cell is exposed* to the action of the complement, which by itself is harmless. As regards complements, what I have said about toxins holds true; they may be regarded as toxin-like substances which *possess* a haptophoric group and a toxophoric group which I call the "zymotoxic" group. *That these* groups are independent of each other is well seen in the case of modified complement—"complementoid," as numerous test-tube experiments have *proved. The* real state of affairs, which has been thoroughly investigated, especially in the case *of* hæmolysins, is this: the intact erythrocytes do not unite with the complement which, however, is anchored by the complex of erythrocyte and amboceptor. The amboceptor and the *complement* stand in direct relationship to one another. I think that the great majority of my colleagues accept the amboceptor theory. It is true that the distributive relation of the complement *in the presence* of the amboceptor is not that of maximum chemical affinity; indeed, we have, *on the contrary,* as a rule an exceedingly loose relationship which perhaps corresponds to a *reversible reaction.* It is owing to the fact that the complement is free, or only loosely united to the amboceptors in the circulation, that at a given moment it is *ready* for use. The maximum stimulus *to action* is rendered possible by the anchoring of the *amboceptor to the erythrocyte,* the avidity of the latter *toward* the complement being thus increased. *This increase* of avidity consists in the chemical affinity of the complementophile group for the complement being carried to its maximum, and represents the gist of our knowledge of the action of the amboceptor. The amboceptor, therefore, exercises the important function of bringing about a specific modification of those conditions existing in the organism which determine the distribution of complements, and which otherwise are not very evident. It causes the complements to become monotropic by its union with the given substance. The complements are thus localised by amboceptors which have previously become united to the substance—cell or otherwise. At the same time this action represents a purposive saving. This is evident from the fact that only in case of need the amboceptor becomes able to combine with the complement, and from the fact that complementoids which, by reason of having lost the zymotoxic group, become incapable of action have at the same time lost some of their avidity for the amboceptor. By this change in the distributive quality of the complement that is associated with the formation of complementoid the sphere of action of the amboceptor is considerably extended. The increase of avidity, which forms the basis of the mode of action of the amboceptor, not only governs the phenomena which occur in the organism, but, since it lends itself to test-tube experiments, also opens up a wide field for serum diagnosis. If we remember that the amboceptors, by their union with the sensitive substances—cells or dissolved bodies—exert such a marked localising influence on the complements, it is evident that in a mixture of an amboceptor and its corresponding antigen, if the presence of the one constituent of the mixture be known, that of the other can be proved by the occurrence of the phenomena of complement-fixation. The peculiar power of the amboceptor to fix a large number of complements is not to be wondered at when we remember the biological function of the amboceptor. This I hold to be, in physiological life, that of seizing upon and elaborating nutritive substances. By its cytophile group the amboceptor is enabled to combine with substances of the most varied kinds provided that they possess fitting receptors. We have, then, merely an increase of purposive function in the fact that the amboceptor is furnished with a host of complementophile groups which enable the most varied kinds of complement to act—it may be simultaneously. This is the consequence of the multiceptive nature of the amboceptor. As regards increase of avidity, the fact that the anchoring of the amboceptor to the cell causes the avidity for the complement to be increased in no way precludes an increase of the avidity of the amboceptor for the cell taking place in consequence of the anchoring of the complement. Besides a few normal amboceptors of the blood serum in which this is observed we find that it occurs in a marked degree in the case of those poisons which act by the united action of two components, the part of the complement being played by lecithin. This power of forming lecithids has been studied in the case of snake and scorpion poisons and bee poison. It is a special characteristic of the formation of lecithids that out of two absolutely non-poisonous substances a powerful poison is formed, which in its biological and physico-chemical reactions differs markedly from the two substances from which it sprang, and does not contain lecithin as such, one fatty-acid residue being removed during the process of formation. I believe that this possibility of the transformation of certain substances, inactive in themselves, from albuminoids to lipoids of powerful action—a transformation which has been proved to occur in the case of snake poisons—plays a prominent part in the processes of the living body and is of importance for distribution and action.

The study of the lecithids from the chemical point of view has shown that in them we have a field in which the phenomena of immunity and those of pure chemistry meet and the hope can therefore be cherished that we may thus obtain a nearer insight into the chemical peculiarities of antigens and antibodies. As to the biological factor in the formation of antibodies, it has been shown that a part of the process takes place in the obscure province of the physiology of stimulation. The receptors of the cell protoplasm are the seat of the process and their regeneration and elimination are the consequence of this. Supposing these processes to occur in the normal organism and to be merely intensified in the case of active immunisation it is possible to understand that antibodies of the most varied kinds may exist in the serum of the normal organism and also to comprehend the processes of immunity by viewing them from the standpoint of the physiology of nutrition and metabolism. One may already by simple means differentiate the multitude of serum substances into antitoxins, amboceptors, agglutinins, precipitins, opsonins, complements, ferments, antiferments, &c., but deeper study of the subject shows that each of these divisions in its turn consists of a multitude of functionally different components, and thus a pluralistic view of the observed phenomena is the only justifiable one. It is the principle of distribution which governs the processes resulting in active immunisation.

The antibodies—the protective substances in the serum—all possess the power of reacting, with maximum chemical energy, with their corresponding antigen, as, e.g., in the anchoring of bacterial cells. This anchoring is a necessary preliminary for further reaction, which may be of the most varied kind. We are acquainted with a number of such haptins, of which the following are examples: (1) the agglutinins, which cause clumping of the cells; (2) the amboceptors, which play the part of carriers in the action of the complement; (3) the opsonins, which render bacteria liable to be seized by the phagocytes, also those haptins which are directed against the contents, or metabolic products, of bacteria; (4) the antitoxins; (5) the anti-endotoxins, which are directed against the endotoxins; (6) the precipitins; and (7) the antiferments, which are directed against certain ferments of the bacterial cells—e.g., pyocyanase. There is no doubt, however, that many more haptins exist.

In order to have an idea of the extreme diversity of the phenomena which cause immunity one must look for other substances whose functions are those which characterise the haptins—the substances, for example, which prevent cell division or those which combat the biological adaptation of bacteria. The possibilities which I have here indicated appear to be limitless and the need for study in this direction is evident. The immunity of an animal is, therefore, explained as being due to the great energy of the cells of its body which are able to appropriate nutritious substances for themselves and in so doing to deprive parasites of them. The opposite condition must be due to a certain disposing influence and immunity of the parasites must be a condition of the cause of infectivity. The bacterial cells may in the same way be immune against haptin substances and may withstand the action of the serum. Thus there exist unstable relations between immunity and infection and between parasite and host, relations which lead to the phenomena of reversible action and still have to be studied.

A Lecture

ON

THE TREATMENT OF CARDIAC DILATATION.

Delivered at the London School of Clinical Medicine on May 6th, 1907,

BY SIR DYCE DUCKWORTH, M.D. EDIN., LL.D.,
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH.

GENTLEMEN,—In discussing this subject with you to-day I am not about to enter at any length into the pathology of such conditions as tend to induce dilatation of the chambers of the heart. We may note in passing that single cavities may be thus affected or more especially involved in a general dilatation. To mention instances—the right ventricle in cases of pulmonary emphysema, the left auricle in cases of mitral stenosis. Again, it may be stated that some measure of hypertrophy is common in dilated hearts, having thus been induced by some valvular defect, long antecedent perhaps, or there may be actual thinning of the walls, which may be flabby or fatty, or yet again altered by fibroid substitution. Any degree of dilatation is an indication of debility. The special significance of it is an incapacity for complete or adequate expulsion of the contents of the involved cavities.

In the case of conjoined hypertrophy with dilatation we are in face of a commencing failure and incompetency of function. Hitherto there have been compensation by overgrowth and increased power to overcome obstruction; now this power is lessening and difficulties with various symptoms announce themselves. The patient with adequate compensation has usually no complaints; directly an inadequacy of propulsive power sets in he seeks relief and is aware that his heart is in difficulties. He has symptoms which are readily recognised; these depend mainly on retention of blood in the several cavities which encourages stretching of the cavities and induces a sense of weight and oppression at the præcordia, dyspnœa, and other symptoms. Physical examination reveals an enlarged area of cardiac dulness. The apex beat may be imperceptible, while the impulse of the right ventricle may be appreciable. The latter is not a bad sign, indicating some reserve of power. The pulse is usually irregular and of low tension. The arteries may be hard and dilated if there has been long antecedent high tension now passed off. Or the pulse may be irregular only after some exertion; a rapid pulse is of ill omen. Auscultation may reveal a mitral systolic murmur due to reflux, or the first sound may be short and loud, the aortic second feeble, with a long first pause. If the sounds are heard close together, with a shortening of the systolic pause, the condition is more serious.

The symptoms are numerous in cases of cardiac dilatation. The brain, being imperfectly bathed in blood, gives rise to languor, irritability, and despondency, often to drowsiness. Syncopal attacks may occur with loss of consciousness. Sleep is disturbed and digestion is imperfect with flatulency. The liver becomes engorged and tumid and the urine is apt to be scanty, albuminous, and loaded with crimson lithates. Dyspnœa is readily induced; œdema of the legs gradually supervenes and they become cold and dusky. Ascites, pleural effusion, pulmonary œdema, and general anasarca may be present. Recumbency becomes impossible and insomnia may be distressing, or the snatches of sleep disturbed by frightful dreams. I have here drawn a picture of the graver degrees of cardiac dilatation such as we frequently meet with in hospital practice. We may meet with minor degrees of it. Such cases are always a source of anxiety, but, as we shall find, a good deal may be done for them by judicious treatment founded on a careful appreciation of the conditions present in each particular case.

Now the main indications for treatment are first to promote the power of the heart's walls, and secondly to relieve the venous engorgement which has arisen from their loss of function. The more pressing duty is to unload the venous system. The question of depletion by letting blood has then first to be considered, and the general condition of the patient as to strength, age, and history of the cardiac ailment will determine our action in this respect. It is seldom that we can be justified in a general venesection from the arm, unless it be in small amount, say, to the extent of six or eight ounces. We shall oftener do well to limit our direct bleeding to the application of six or eight leeches to the epigastric or hepatic region. This may not secure more than two or three ounces of blood but the process of leeching now so much neglected, is a source of more relief and comfort than the mere amount of depletion would indicate. There is a marked counter-irritant action induced by leeching which has, doubtless, some beneficial effect. Certainly the relief thus afforded is very marked, the pain, tumidity, and oppression being greatly dispelled. A poultice should be placed over the leech bites and while this encourages further depletion it induces a favourable hyperæmia over a large surface. We may next try to relieve the hepatic congestion further by such purgation as the particular patient can bear with impunity and in this way help to relieve the general systemic venous engorgement. By far the best purgative here is mercury in some form. To urge bleeding and the use of mercury in these days may appear to some of you as a revival of old and effete practices. We are supposed, especially by the public, to have abolished all such methods now and to employ simpler and better ones. Such treatment is thought to be weakening and blood to be too precious to shed in the twentieth century. In my opinion, this is nonsense, and not to employ such measures is to be void of all wise clinical instinct and to be deprived of the only real methods of affording relief to our patients. It is hard enough now to implant this knowledge in the mind of modern students. Their minds are so full of imparted ideas about toxins, microbes, opsonic indices, neurons, and extra-pharmacopœial remedies that there is no room to hold precious knowledge of approved clinical methods and of the virtues of pharmacopœial drugs, and with all this modern development we are fast losing the old-fashioned *art* of medicine and have too little teaching of it in the schools. The action of mercury is not merely a purgative one but it is the best agent for lowering the resistance so commonly existing in these cases in the arterioles and capillaries and thereby relieving the labour of the cardiac walls which is exhausting them. The sources of this obstruction probably lie in the liver or alimentary canal and are cleared away by mercurial influence. Calomel, blue pill, or grey powder (with colocynth and henbane) in doses of from two to five grains should be given at once overnight, followed by a saline aperient in the morning, and repeated for one or two nights, subsequently being taken twice or thrice a week according to the effect produced. You notice that I make no mention so far of digitalis or other tonic for the labouring heart. These are not the primary needs. Relief will be already largely afforded in all directions by the treatment and we may then begin with Baillie's well-known combination of blue pill, squills, and digitalis. By day we may give tincture of digitalis with nux vomica, ammonia, and compound spirit of ether in mixture.

The dietary is important. It should be rather dry if it can be borne. Small feeds every three or four hours with solid or semi-solid food are best. Much fluid with the meal is objectionable, oppressing the stomach and the heart. Between meals the patient may take coffee, if possible, and fresh lemonade containing bi-tartrate of potassium one drachm to the pint. This is especially useful in removing any dropsy. If solid food is loathed we may use beef essence or jelly, or fish, pounded meats, scraped ham or chicken, or milky pudding in small quantities. Alcohol is commonly necessary, old brandy being the best form in which to give it. It is seldom necessary to exceed two or four ounces in the 24 hours. Two ounces of cold or hot water or of some alkaline water may be given at intervals if there is much thirst and a larger quantity of hot water early in the morning is useful to wash out the alimentary canal and to promote a more free diuresis which should be looked for. When the heart is relieved we generally find a more free urinary flow to occur. Later we may employ iron with strychnine or phosphoric acid with nux vomica as appropriate tonics. Ascites, if urgent, may demand tapping, and extreme œdema of the legs, if it does not yield to the remedies just mentioned, must be dealt with by Southey's trocar, careful aseptic precautions being always observed. It may take several hours to relieve the abdomen by this method but it is the safest one to adopt. There is often difficulty in securing adequate rest and sleep at night. Recumbency is seldom possible and if propping up by pillows is not adequate to secure easy respiration the patient is better allowed to sit in a properly adapted chair with support for the arms and a rest arranged for the head to lean somewhat forward. A full dose of compound spirit of ether, with 10 or 15 minims of a solution of morphine hydrochloride, may prove very soothing in the worst forms of restlessness and insomnia with dyspnœa.

Under the influence of these measures it is often remarkable how much improvement may be wrought in these distressing conditions. Yet the patient is always in danger of relapses unless he is extremely prudent in all particulars. In hospital patients we see the worst symptoms in such cases. They secure marked relief, but a return to work or exposure to unwholesome environment and the varieties of the *res angusta* of the poor soon induce a recurrence of the original symptoms and they return to die. For the better placed in society we may hope for a happier outcome with continued skilled supervision of their daily lives. But in them a time arrives when the measures we have enjoined fail to bring relief—the myocardium is worn out, recuperation is at an end, and a fatal issue is inevitable.

The moral of cardiac dilatation lies far back in the history of these cases. Prevention is better than cure. By adequate treatment of the disease which is largely productive of this state—rheumatic fever—and by the adoption of habits which avert premature disease in the valvular structures of the heart and the arterial tunics generally we can alone stave off the ultimate outcome of the progressive failure and inadequacy of function in the vascular system which lead up to the condition we have been considering to-day. Strain, rheumatic fever, syphilis, intemperance in alcoholic drinks, over-eating, and over-indulgence in anything are the main factors, and most of them may be avoided if men and women will but live in what the late Sir Andrew Clark termed "physiological righteousness."

THE CAUSES OF COLITIS, WITH SPECIAL REFERENCE TO ITS SURGICAL TREATMENT.[1]

WITH AN ACCOUNT OF 36 CASES.

By J. P. LOCKHART MUMMERY, M.B. Cantab., F.R.C.S. Eng.,

HONORARY SURGEON, KING EDWARD VII. HOSPITAL FOR OFFICERS; ASSISTANT SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM AND TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

A great deal of attention has been paid within recent years to the subject of colitis, more especially, perhaps, on the continent, and in 1905 Dr. W. Hale White brought the subject prominently before the profession in this country by the publication of his study of 60 cases. Although colitis is generally looked upon as belonging to the province of the physician rather than that of the surgeon, many cases of colitis come under the care of the surgeon.

Colitis has been described under many different names by different authors. Such names as colica mucosa, tubular diarrhœa, membranous colitis, and muco-membranous entero-colitis are only a few of the names which have been used to describe what is without doubt the same condition. My cases do not differ in symptomatology in any important particular from those recorded by other writers under one or other of these different names. The essential symptom in all cases is the presence of excess of mucus in the stools in the form of casts (complete or broken up), shreds, or large glairy masses. In addition bleeding, intestinal sand, diarrhœa, and acute attacks of abdominal pain are common accompanying symptoms.

From the study of my own cases I have been driven to the conclusion that colica mucosa, by whatever name it is called, has no claim to be described as a disease any more than has diarrhœa or hæmatemesis, but that it is a symptom or condition which may result from a number of different diseases of the colon of widely different characters. This is not, I think, a new hypothesis, as although the point has not been specially emphasised before it is the logical conclusion to be drawn from such collections of cases as those of Dr. Hale White and some of the German writers on the subject. I shall attempt to show that in the great majority of cases a lesion or lesions can be demonstrated which it is only reasonable to suppose is the cause of the condition.

Until a few years ago our only means of knowing the condition of the colon in cases of colitis was by a study of the symptoms and an examination of the abdomen and of the discharges, aided sometimes by what was seen of the outside of the bowel when an operation was performed or of its interior when the patient had died from some other cause when suffering from colitis. Within the last four or five years, however, the technique of examining the lower bowel by means of instruments has so much improved that we have been enabled to examine accurately the interior of the lower bowel in all those cases where symptoms of colitis were present, and in this way much has been learned as to the causes of colitis which was hitherto unknown.

The most important advance in our knowledge of these cases has been due to the invention of the electric sigmoidoscope. This instrument enables us to see the condition of the mucosa in the rectum and sigmoid flexure and to compare the condition found in health with that found when symptoms of colitis are present. It has rendered untenable the theory of Professor Nothnagel that colitis is a neurosis unaccompanied by local lesions of the bowel, for in quite a large proportion of the cases definite local lesions can be found to explain the symptoms.

A point of no little importance which a systematic sigmoidoscopic examination of the bowel in cases of colitis has brought out is that the causes for the condition are in many cases confined to the lower part of the sigmoid flexure and rectum. This fact was pointed out by Tuttle and Kelly and I have been able repeatedly to verify the truth of their observations. It is, after all, not surprising that this should be so as the portion of the large intestine which is most subjected to abnormal conditions is the sigmoid flexure and rectum; it is here that stagnation and pressure occur in constipation and there can be no doubt that constipation is by far the commonest antecedent of colitis; it is here that any irritant material, be it solid or liquid, will collect and tend to stagnate if present in the large bowel; and it is here that the greatest amount of traumatism from the passage of hardened fæcal masses will be felt. In fact, those portions of the large bowel which are most liable to injurious influences are the two dependent ends, the cæcum and the sigmoid flexure, and it is here that disease when it attacks the large intestine is most frequently found. We should therefore expect that the chief lesion would be situated either in the cæcum or in the sigmoid flexure and, as I shall attempt to show, this is the case.

Symptoms.—Diarrhœa was a prominent feature in a majority of the cases and in some it was most severe. In Cases 16, 20, and 23 there were at one time as many as from 20 to 25 stools per diem. The diarrhœa was usually the symptom which first caused the patient to seek medical advice. In almost all the cases there was an antecedent history of constipation quite irrespectively of whether an inflammatory lesion or a new growth was found at the examination.

Bleeding occurred in 22 out of the 36 cases. In most of the cases in which there was bleeding this could easily be accounted for by the fact that definite ulceration was present in the bowel. In some, however, no definite cause for the bleeding was discovered. In two of the cases of new growth, Cases 18 and 19, there was no bleeding at all. This shows, I think, that bleeding cannot be considered characteristic of new growth.

Mucus was present in the stools in all the cases in sufficient quantities to draw the patient's attention to it. In some cases very large quantities of mucus were passed so that the stools consisted sometimes of little else. The mucus was in some cases thin and almost fluid, in others thick and gelatinous or in shreds and strings. Large mucous casts were present in the stools in eight of the cases, and I would especially draw attention to the fact that casts were seen in two of the cases, Cases 3 and 21, which were due to malignant disease of the bowel. These two cases are, I think, worth recording in detail.

Case 3 was that of a woman who for five years had suffered from acute attacks of pain in the abdomen followed by the passing of large mucous casts per *anum*. There had been some bleeding at times during the last 12 months. On examining her I found that she had a large growth in the sigmoid flexure. The growth was quite inoperable and she died a few months after I saw her.

Case 21 was that of a man who had only had symptoms of bowel trouble for six months. On several occasions he had passed mucous casts several inches in length. On examining him I found a large malignant growth in the sigmoid flexure and a mass of enlarged glands in the mesorectum. No operation was possible in his case.

Loss of weight was quite as common in the non-malignant as in the malignant cases. It was most marked in those cases associated with severe diarrhœa.

Intestinal sand was seen in the stools in two cases (Cases 2 and 20). In both it was a fine yellowish-red sand when passed but it became black if left for some days. The sand was analysed in both cases and was found to consist of carbonates and phosphate of calcium and ammonium but no cholesterin. It is an interesting fact that in Case 2 the patient also occasionally passed uric acid gravel in the urine. In both cases very severe attacks of abdominal colic were associated with the appearance of the sand.

The interesting condition of enterospasm was present in one of my cases (Case 20). Enterospasm is a localised contraction of the bowel, often resulting in a temporary intussusception. It most usually occurs in the descending colon or sigmoid flexure and is accompanied by extreme pain localised to that portion of the abdomen in which the contracted portion of bowel lies. The spasm may involve a large length of bowel according to some authorities, but in those cases in which I have met with it only an inch or two of bowel has been contracted. In my patient there were attacks of extreme abdominal pain and a hard tumour about two inches in length could be felt in the sigmoid flexure. I examined the patient very carefully, as I suspected that her colitis might arise from a growth in the sigmoid flexure. She had constant diarrhœa with stools consisting of blood and mucus. The tumour might have easily been mistaken for a growth, but I found that it always disappeared when the pain ceased and was always present when a fresh attack of pain occurred. The contracted portion of bowel always occupied the same position and I came to the conclusion that the spasm resulted from an ulcer in that portion of the bowel, as there was tenderness over that spot when the contraction was not present. The patient recovered as the result of a careful dieting and irrigation.

---

[1] A paper read before the Royal Medical and Chirurgical Society on June 11th.

My colleague at St. Mark's Hospital, Mr. F. Swinford Edwards, had a most interesting case of the same sort. He opened the abdomen to explore for a tumour in the sigmoid flexure and on drawing out the bowel found a contracted band about two inches in length resembling a local intussusception. While he was watching it disappeared and again reappeared. Enterospasm appears to result from some local irritation within the bowel. The irritation may result from an ulcer within the bowel or from a hardened fæcal mass or concretion.

The examination of the patient.—A patient suffering from colitis cannot, as a rule, be properly examined in the consulting-room or out-patient department of a hospital. The sigmoid flexure is normally full of fæcal material and special means are necessary to empty it. The patient should be confined to bed and the rectum and sigmoid flexure thoroughly emptied by aperients and enemata administered by a skilled nurse. The examination with the sigmoidoscope is not painful and, as a rule, causes but little discomfort, so that an anæsthetic is not required in most cases. The greater part of the sigmoid flexure can be readily examined and the condition of the mucosa observed. The sigmoidoscope, like the cystoscope or laryngoscope, requires practice before it can be properly used, but in skilled hands it is perfectly safe and the view of the parts obtained with it is all that could be desired. The abdomen should, of course, be examined, especially the appendix area and the left flank. The stools should also be examined and in some cases a microscopical or bacteriological examination made of the abnormal constituents.

Cases of colitis in which lesions are present within the bowel.—I shall attempt to show that some lesion either within the bowel or external to it, but involving it, can be demonstrated in the majority of cases of colitis and that the recent improved methods of examining the bowel have proved that what is generally called colitis is a symptom of some local lesion of the bowel. I do not wish to assert that whenever we find an abnormal condition of the mucosa we are necessarily at once to look upon it as the cause of the colitis. I do not think that the gravity of the lesion in some of the cases is sufficient to justify this view, and it may be that the appearances are but secondary to some more serious lesion at a higher level. That this may occur is evidenced by the following case which I saw in consultation with Mr. A. W. Mayo Robson. The patient was an elderly gentleman who for many months had been passing large quantities of blood and mucus in his stools. An examination with the sigmoidoscope was made and revealed the presence of numerous small follicular ulcers scattered about on the mucous membrane of the rectum and sigmoid flexure. There seemed to be sufficient ulceration present to account for his symptoms and he was treated by irrigation and injections upon this assumption. After a few weeks, however, although the ulcers had healed, he was still passing blood and mucus in considerable quantities. He was again examined with the sigmoidoscope and on this occasion a cancerous ulcer was detected very high up in the sigmoid flexure. This was subsequently excised by Mr. Mayo Robson. This case shows the importance of a thorough and careful examination and that the presence of definite ulceration in the bowel does not exclude the possibility of a more serious lesion at a higher level.

It will be observed by reference to the table of cases that in the majority of cases of colitis the lesions discovered on examination were of a chronic inflammatory nature. This is opposed to the views expressed by Nothnagel who believed colitis to be in most cases a neurosis.

In my series of cases a definite inflammatory condition of the mucosa was found in 24 out of the total of 36 cases, or in 66 per cent. The appearance of the inflammatory condition found varied very considerably in the different cases and varied sometimes in the same case at different times. In all the cases the inflammation was of a chronic character and appeared to involve only the mucous membrane or submucous cellular tissue.

The most usual appearance was for the mucous membrane to be injected and bright red; the normal mucous membrane is of a pale pink colour. The surface was dull, having lost its normal glistening appearance, and often granular. This granular condition closely resembles that seen in granular pharyngitis. In many of the cases the mucous membrane looked as if its surface had been rubbed off with sand paper. It bled readily if touched with the instrument and bleeding spots could often be seen apart from this. Scattered about on the mucous membrane there were irregular patches of yellowish white adherent mucus which often gave a very characteristic appearance to the bowel. Occasionally a very extensive area of bowel was affected, and in some cases the whole of the visible portion of the sigmoid flexure was involved. The inflammation was always most marked at the flexure and on the valves of Houston. In some of the cases, more especially when an examination was made during acute attacks, the condition resembled an extensive superficial ulceration of the mucosa.

In addition to the granular condition of the mucous membrane there was definite ulceration in seven of the cases. The ulcers were irregular in outline, quite shallow, and with a granular base. These ulcers were often very numerous and sometimes extended throughout the entire sigmoid flexure and rectum. To turn to the cases in which ulceration is found. The degree of ulceration which may be found in a case with symptoms of colitis varies very considerably. Thus in some cases I have seen a few shallow ulcers at irregular intervals, situated chiefly in the rectum or in the lower portion only of the sigmoid flexure. In other cases these ulcers were so numerous as to cover most of the surface of the rectum and sigmoid flexure, the normal mucosa standing out in contrast to the background of ulceration. Even in such cases, however, the ulceration may be so shallow as to involve the superficial layers only of the mucosa and it is important to distinguish between this variety and that in which the ulcers are numerous and deep. The latter is a much more serious condition; the ridges of healthy mucous membrane between the ulcerated areas here appear like polypi, so prominently do they appear to stand up from the surrounding ulcerated areas.

As a rule, ulceration is found in those cases of colitis where severe symptoms exist, but this is not always the case and I have seen well-marked ulceration in cases where the symptoms were mild and no ulceration in cases where the symptoms would lead one to suppose that severe ulceration was present. The ulcers as a rule in the more chronic cases are found at those points where local irritation or traumatism is likely to occur—thus, at the recto-sigmoidal junction, in the bottom of the sigmoid pouches, and on the surfaces of the rectal valves. These shallow ulcers must be distinguished from the ulceration found in cases of acute ulcerative colitis or dysentery. In the latter conditions the whole thickness of the mucosa is destroyed and if healing occurs there is of necessity considerable scarring.

In one case I had the opportunity of examining a patient who had recovered from a severe attack of dysentery and the white stellate-looking scars left by the healed ulcers could be seen all over the rectum and sigmoid flexure. In the shallow form of ulceration, however, which I have seen associated with chronic colitis the ulcers readily heal with suitable local treatment and no scarring results. The symptoms during an acute attack may, however, be very severe, and it is important to distinguish this form of ulceration from the deeper and more serious ulceration, as the prognosis, while good in the former, is not so favourable in the latter.

CASE 36 is of particular interest. The patient was a man, aged 41 years, under the care of Dr. G. Baynton Forge. He had always been a healthy man and, with the exception of one or two slight attacks of diarrhœa, had had no serious illness until recently. In July, 1906, after a period of overwork he was suddenly taken ill with severe diarrhœa. This got worse and he began to pass blood and mucus in considerable quantities. In spite of rest and treatment there was no improvement in his condition. He was for some weeks under treatment in Maidstone Hospital but without much benefit. When I first saw him in February of this year he was passing eight or nine stools a day and there was much mucus and blood. He had lost two stones in weight since the onset of his illness. He looked thin and had a pale and sallow complexion. I took him into St. Mark's Hospital and examined him with the sigmoidoscope under an anæsthetic. The whole of the mucous membrane of the rectum and of the lower part of the sigmoid flexure was rough and very coarsely granular, suggesting the appearance seen in granular pharyngitis. There was extensive ulceration of the mucosa, TABLE OF CASES OF COLITIS.

No.	Sex.	Years of age.	Symptoms.	Duration.	Condition found.	Remarks.
1	M.	50	Attacks of pain; mucus; bleeding.	3 years.	No cause found.	—
2	F.	46	Severe attacks of pain; mucous casts; intestinal sand.	9 months.	"	Patient much better but is subject to relapses.
3	F.	51	Severe pain during attacks; mucous casts passed after attacks; some bleeding during last 12 months.	5 years.	Cancer in sigmoid flexure.	Inoperable; the patient died.
4	F.	46	Mucus after attacks of pain; diarrhœa alternating with constipation.	Some years.	*Nothing found.*	—
5	F.	22	Continuous diarrhœa; mucus.	10 years.	Mucous membrane red and congested; upper limits not defined.	—
6	M.	40	Excessive mucus in stools; pruritus.	6 years.	Hypertrophic catarrh with œdema of submucous tissue; upper limits not defined.	—
7	M.	42	Blood and mucus.	3 months.	Hypertrophic catarrh; upper limits not seen.	
8	M.	78	Blood and mucus with severe diarrhœa.	3 weeks.	Nothing abnormal found.	Got better but had a relapse *five months* later.
9	M.	26	Bleeding and diarrhœa; much pain at times; mucus in small quantities.	3 years.	Hypertrophic catarrh; œdema of mucous membrane; ulceration.	Has been operated upon for piles three times in two years.
10	F.	35	Large casts passed frequently; mucus constantly present in stools.	2 years.	Adhesions binding down sigmoid flexure; two and a half years ago a large abscess at the back of the pelvis was opened from the abdomen and drained; previously to this a normal appendix was removed.	—
11	F.	45	Passes mucous casts and blood.	4 years.	Granular chronically inflamed condition of mucous membrane, most marked in rectum but the upper limits not defined.	—
12	M.	23	Bleeding, diarrhœa, and pain of a spasmodic nature; mucus passed in large quantities.	6 years.	Mucous membrane granular and bleeds if touched; several small polypi seen high up.	—
13	M.	35	Diarrhœa and passing mucus in large quantities.	3 years.	*Nil.*	—
14	F.	17	Passing mucus and blood.	3 years.	Well-marked hypertrophic catarrh confined to rectum and lower part of sigmoid flexure.	—
15	M.	32	Constant diarrhœa and passing large quantities of mucus.	8 months.	Mucous membrane red, swollen, and granular; numerous shallow ulcers; mucous membrane normal above middle of sigmoid flexure.	Relapse five months later.
16	F.	32	Diarrhœa and passing mucus in large quantities; bleeding occasionally.	3 years.	Congested and granular condition of mucous membrane; upper limits not defined.	Rapid improvement; relapse seven months later.
17	F.	29	Pain, diarrhœa, and mucus.	1 year.	Much swelling and congestion of mucous membrane; narrowing of bowel from adhesions seen high up; laparotomy revealed adhesions of sigmoid flexure to appendix.	The patient had previously suffered from proctitis.
18	F.	42	Diarrhœa; mucus in considerable quantities; no bleeding.	3 months.	Cancer in sigmoid flexure.	Inoperable.
19	M.	63	Diarrhœa; no bleeding; mucus.	1½ years.	Papilloma high up in rectum; malignant at base.	Excision; recovery.
20	F.	39	Diarrhœa; much mucus; casts at times; bleeding; enterospasm; intestinal sand.	10 years.	Catarrhal inflammatory condition of rectum and sigmoid flexure; upper limits not defined.	—
21	M.	52	Much mucus; mucous casts; bleeding on one or two occasions slightly.	6 months.	Cancer in sigmoid flexure.	Inoperable.
22	M.	65	Diarrhœa; much mucus; some bleeding.	6 months.	Some congestion of mucous membrane.	—
23	M.	30	Diarrhœa; bleeding; much mucus.	3 years.	Extensive shallow ulceration, most marked in lower loop of sigmoid flexure and in rectum; upper limit not seen.	—
24	M.	28	Diarrhœa; much mucus; bleeding.	3 years.	Shallow ulcers in rectum and sigmoid flexure; granular mucous membrane; upper limits not seen.	—
25	M.	45	Diarrhœa and mucus in large quantities; blood occasionally.	Several years.	Catarrhal inflammation of rectum and sigmoid flexure. Some adhesions binding down the latter.	Local condition hardly accounts for symptoms.
26	M.	40	Diarrhœa and mucus.	1½ years.	Granular condition of mucous membrane and catarrhal inflammation; upper limits not defined.	—
27	F.	39	Mucous casts.	3 years.	Retroflexed uterus pressing upon the rectum and hypertrophic catarrh.	Ventrofixation of uterus performed.
28	F.	37	Mucous casts; bleeding.	15 years.	Catarrhal inflammation of rectum and sigmoid flexure.	—
29	M.	58	Diarrhœa and mucus.	8 months.	Nothing found.	—
30	M.	41	Diarrhœa; mucus.	2 years.	Slight catarrhal inflammation in rectum and sigmoid flexure.	Condition found hardly accounts for symptoms.
31	M.	40	Diarrhœa; mucous casts; bleeding.	3½ years.	Chronic inflammation with shallow ulcers in rectum and last inch or two of sigmoid flexure.	—
32	M.	53	Diarrhœa; mucus; bleeding.	6 months.	Cancer in sigmoid flexure.	Operation refused.
33	M.	50	Diarrhœa; mucus; bleeding.	9 months.	Catarrhal inflammation of rectum and sigmoid flexure and piles.	—
34	M.	65	Diarrhœa; mucus; bleeding.	1 year.	Ulceration of sigmoid flexure and cancer in middle of sigmoid flexure.	Growth excised.
35	M.	44	Diarrhœa; blood and mucus.	2 years.	Small cancerous growth in sigmoid flexure.	Growth excised and end-to-end anastomosis performed; recovery.
36	M.	41	Diarrhœa; blood and mucus.	7 months.	Ulceration of rectum and sigmoid flexure; mucous membrane very granular; fibrous band causing kink in the flexure at about its centre.	Exploratory laparotomy revealed a band fixing the middle of the sigmoid flexure; recovery.

the ulcers being irregular in outline and shallow, involving only the superficial layers of the mucosa. Above the centre of the sigmoid flexure the ulcers were much less numerous. On digital examination some enlarged glands could be felt in the meso-rectum and abdominal palpation revealed a distinct thickening in the left iliac fossa. He was treated by large oil injections into the colon and irrigation with potassium permanganate for a fortnight. Under this treatment the ulcers healed and all the symptoms cleared up. But as there was still a distinct thickening in the left iliac fossa and as I did not feel certain that there might not be a growth higher up in the sigmoid flexure than we were able to see with the sigmoidoscope I thought it advisable to perform exploratory laparotomy. On opening the abdomen I found there was no growth but the walls of the sigmoid flexure were very much thickened, so much so that the bowel in places felt like a thick indiarubber tube. There were also numerous enlarged glands in the meso-sigmoid. In the centre of the sigmoid flexure there was a thick fibrous band about three-quarters of an inch broad binding down the sigmoid flexure into the left iliac fossa and causing a kink in the bowel. The transverse colon was normal, as were also the cæcum and appendix. All the other organs were normal. I divided the fibrous band and closed the abdomen. After he had got over the operation the previous treatment was continued with the addition that he was given von Noorden's diet, and he was discharged apparently quite well at the beginning of April. With the sigmoidoscope it could be seen that all the ulcers had healed and although the surface of the mucosa was still rough and granular it was decidedly better than at the first examination.

In four cases there was a chronic hypertrophic catarrh associated with œdema of the submucous tissue. On examining such a case with the sigmoidoscope the mucosa is seen to be much paler than normal and to be thrown into numerous folds or concentric rings. The mucous membrane bulges forward into the bowel lumen, giving the appearance of a partial intussusception at the point examined. The mucous membrane is thickened and œdematous, though its surface retains its normal shiny appearance. The sigmoidoscopic appearances are very characteristic and cannot be mistaken. This condition was associated in all my cases with excessive secretion of gelatinous mucus.

Severe pruritus was present in two of the cases and the patient in Case 6 consulted me on this account. This patient got better after regular irrigation of the bowel with an alkaline lotion and the use of astringent injection of krameria, and his pruritus, which had existed for many years, was cured. I have seen this hypertrophic catarrhal condition of the mucosa in two cases of pruritus in which the patient did not give a history of colitis.

Cancer as a cause of colitis.—In seven (Cases 3, 18, 19, 21, 32, 34, and 35) out of my series of 36 cases the colitis was due to a tumour within the bowel. In all of these cases there was considerable doubt about the diagnosis previously to the discovery of the tumour and several of the patients had previously been under treatment for colitis. In looking through my cases of cancer of the rectum I find there are several in which the symptoms were those of colitis rather than cancer, but I have not included them as there was at no time any doubt about the diagnosis as a digital examination revealed the true state of affairs.

It is impossible from the symptoms alone to distinguish those cases of colitis which are due to cancer from the other forms. The presence of blood in the stools is of no value. In Cases 18 and 19 there was no blood and only a very small amount of blood on two occasions in Case 21. Definite mucous casts may be passed in cases of cancer, as is shown by Cases 3 and 21. In both these cases typical mucous casts had been passed on several occasions. The age of the patient does not help us much, as in Case 18 the patient was only 42 years of age, and only two of the others were over 55 years, while the average age for all the cases is 43 years. The time during which the symptoms have existed will not exclude cancer, as in Case 19 symptoms had existed for one and a half years and in Case 3 for five years.

Case 3 is a remarkable one. The patient had had symptoms of a severe colitis for five years; she had passed mucous casts of the bowel after acute attacks of abdominal pain. She had laparotomy performed twice. What was found on the first occasion I do not know but at the second operation an adherent ovarian cyst was removed. When I saw her she had a malignant growth at the upper end of the sigmoid flexure. A short-circuiting operation was subsequently performed by another surgeon but she died from intestinal obstruction shortly afterwards.

In Case 18 a large growth in the sigmoid flexure was discovered on examining the patient with the sigmoidoscope. I subsequently performed colotomy after finding that the growth could not be removed. In Case 19 I removed the growth, which was a large papilloma becoming malignant at its base, and the patient has remained well since, a period of over two years. In Case 21 the growth was inoperable. In Case 32 the growth was seen high up in the sigmoid flexure through the sigmoidoscope. The patient unfortunately refused operation. In Case 34 the growth was situated 22 centimetres from the anus. It was seen through the sigmoidoscope and could not have been diagnosed otherwise. This patient had numerous small ulcers scattered over the mucous membrane of the rectum and sigmoid flexure below the growth. Mr. Mayo Robson subsequently excised the growth from the abdomen and anastomosed the ends of the bowel.

Case 35 is of particular interest. The patient was an exceedingly neurotic man, aged 46 years, who was sent to me by Dr. G. Baynton Forge. For nearly two years he had been under treatment by different practitioners for ulcerative colitis and during that time he had been passing blood and mucus in his stools almost continuously. There were no constipation and no difficulty in keeping the bowels open at any time. He had been putting on weight slowly for about two months before I saw him. On examining him with the sigmoidoscope I found a small malignant growth, of about the size of a shilling, growing from the anterior wall of the sigmoid flexure about six inches above the upper end of the rectum. The mucous membrane above the growth was inflamed and resembled the condition seen in non-malignant cases of colitis. I excised the growth and a V-shaped portion of the adjacent mesentery from the abdomen and joined the ends of the bowel end to end by simple suture; the abdomen was closed without drainage. He made a good recovery and returned home in good health about one month after operation. A microscopical examination of the growth showed that it was an ordinary medullary carcinoma.

Among the rarer causes of chronic colitis which have been recorded mention must be made of actinomycosis of the colon, two cases of which are recorded by Beck. Another rare local condition is tuberculosis, of which seven cases are recorded by Beck.

Multiple adenomata of the large intestine.—This is a very curious condition and only a comparatively small number of cases have been recorded. These adenomata are present in great numbers; in some cases the entire mucosa of the large bowel is covered over with them. In some of the cases only a portion of the bowel is affected, the commonest situations being the sigmoid flexure and rectum. The symptoms are those of a severe colitis. There is often much blood in the stools, but in some of the cases there has been none. One of the most remarkable cases of this disease was that reported by Lilienthal; the whole colon was affected and the patient was ultimately cured by excision of the entire large intestine. A case was reported recently by Dr. Mabyn Read, and the specimen of a case was shown at the Leicester meeting of the British Medical Association in 1905 by Mr. E. Stanmore Bishop. Dr. Carey P. Coombs has also recently reported a case.

Causes of colitis outside the bowel.—Colitis may result from adhesions due to an acute pericolic inflammation. Cases of acute pericolitis are not uncommon and several well-authenticated cases have been described, notably by Dr. H. D. Rolleston. In one of my cases the patient had an acute attack of abdominal inflammation and a large abscess in connexion with the sigmoid flexure and rectum was found and opened through an abdominal incision. Shortly afterwards she commenced to suffer from well-marked symptoms of mucous colitis, which increased up to the time I saw her three years after the operation. Everything pointed to the adhesions around the sigmoid flexure and binding it down into the pelvis as the cause of her symptoms.

Uterine displacement may be a cause of colitis by interfering with the action of the sigmoid flexure and the evacuation of its contents into the rectum. A retroflexed uterus acts like a ball valve in blocking up the posterior pelvic outlet and causes a very considerable degree of obstruction in some cases. In Case 27, in which laparotomy was performed for colitis, the retroflexed uterus could be seen to block the posterior pelvic outlet almost completely and the sigmoid flexure above the point of constriction by the uterus was greatly distended and hypertrophied. Ventrofixation of the uterus resulted in considerable improvement in this patient's condition.

Beck out of 500 cases of chronic colitis found chronic inflammatory lesions in the neighbourhood of the colon in 394.

Colitis and appendicitis.—It is difficult to say exactly what is the association between appendicitis and colitis. The most usually accepted view is that colitis may result from a chronically inflamed appendix. Dr. H. A. Caley has expressed the view that appendicitis often results from colitis. The probability would seem to be that both appendicitis and colitis result from the same causes—namely, incorrect dieting and constipation. That appendicitis can be the cause of colitis is, I think, unquestionable. The evidence in favour of this view is very strong. A certain degree of colitis is usually present in all cases of acute appendicitis, though no definite symptoms of the conditions may show themselves.

In exactly what way appendicitis causes colitis we do not know, but it seems probable that it may produce it in several ways. 1. Appendicitis is generally accompanied by inflammation of the ascending colon and cæcum, and in some cases this inflammation of the colic mucosa may spread into the transverse colon and even reach the sigmoid flexure. As Mr. C. B. Lockwood has pointed out, it is not uncommon during the operation for appendicitis to find that the inflammation has spread into the ascending colon. 2. Appendicitis may also cause colitis by the formation of adhesions between the appendix or cæcum and the sigmoid flexure. These adhesions by interfering with the lumen of the gut either through direct constriction or by causing abnormal flexures and angles may result in a local inflammatory process being set up and the symptoms of colitis subsequently develop. The first result of such adhesions is usually constipation to be followed in a shorter or longer time by diarrhœa and the passage of mucus. This had occurred in Case 17. On opening the abdomen I found the appendix adherent at its tip to the sigmoid flexure and several adhesions binding down the sigmoid flexure and preventing it from rising out of the pelvis. Considerable improvement followed removal of the appendix and separation of the adhesions. 3. It would seem probable that a chronically inflamed appendix may cause symptoms of colitis by the frequent discharge of septic material into the bowel. It has become customary to describe the colon and rectum as septic channels, though there is no justification for this. As a matter of fact, septic organisms are not at all usually numerous in the large intestine and the pathogenic flora of the mouth is far more numerous than that of the rectum and colon. Even the skin is a more common habitat for septic organisms than the colon. It is not surprising therefore that a chronically inflamed appendix which is continually discharging septic organisms into the bowel may be the cause of colitis, just as we know that carious teeth and septic conditions of the mouth can cause gastritis.

We have very positive evidence that removal of an inflamed appendix will in many cases lead to a complete cure of colitis. In Mr. Lockwood's paper already referred to he records three such cases where the symptoms of colitis cleared up entirely after the removal of an inflamed appendix. Dr. Hale White, in his valuable paper on membranous colitis, records four cases in which the appendix was removed for symptoms of colitis. In only one of these, however, did a cure of the colitis follow the operation. It is noteworthy, however, that the successful case is also the only one of which it is recorded that the appendix was found to be diseased. Beck found a chronically inflamed appendix to be the cause of colitis in a considerable number of cases of chronic colitis and believes it to be a common cause of colitis. Tuttle records five cases of chronic colitis cured by the removal of an inflamed and adherent appendix. Olmsted of Ontario records a case of severe mucous colitis in which rapid improvement followed the removal of a congested appendix, and Amatt of Ontario records two similar cases.

Adhesions of the bowel as a cause of colitis.—There is every reason to believe that adhesions binding down the large bowel and interfering with its normal movements are an important factor in the causation of colitis. In a great many cases of severe and intractable colitis for which an exploratory laparotomy has been performed adhesions binding down the sigmoid flexure, and more rarely the cæcum or splenic flexure, have been found, and their division has been followed by a cure of the condition, though not infrequently the adhesions have re-formed at a later date with a recurrence of the old symptoms. These adhesions have been supposed to arise from long-continued constipation, but it is difficult to understand how adhesions can arise from constipation alone and it seems much more probable that the presence within the bowel of hard retained fæcal masses has set up a local inflammation or definite ulceration and that the adhesions to neighbouring parts have resulted from the local peritonitis thus caused. This seems all the more likely, as adhesions are usually found in those portions of the bowel, such as the sigmoid flexure, ascending colon, and cæcum, where retention of fæcal material most easily occurs. I believe local simple ulceration of the mucosa of the large bowel is much commoner than is generally supposed. I have often observed simple ulcers in the sigmoid flexure with the sigmoidoscope in cases of chronic constipation, though no symptoms of ulceration were present.

The adhesions interfere with the normal peristaltic movements of the colon and a chronic catarrhal inflammation of the mucosa is set up at the points where adhesions have formed.

A floating kidney has been supposed to cause colitis and Tuttle records two cases apparently cured by fixation of an exceptionally mobile kidney. In those cases of colitis associated with a moveable kidney which have come under my observation I have seen no reason to suppose that the condition of the kidney was in any way the cause of the colitis.

It is interesting to observe that symptoms of colitis may occur in cases of abdominal aneurysm. In such cases the colitis apparently results from the pressure of the aneurysm upon some contiguous portion of the large bowel. Tuttle records six cases of abdominal aneurysm in which there was well-marked and intractable mucous colitis.

In six of my cases no local cause for the colitis could be discovered and in two cases (Cases 25 and 30) the local lesion did not seem sufficient to account for the symptoms. In Case 29 in which no local lesion was found the subsequent history of the patient pointed to the presence of a malignant growth high up in the colon, but I have since heard that he is still alive, though not any better, one and a half years after he was examined. In Case 25 it seemed probable that the chief lesion was higher up in the sigmoid flexure than we were able to see. There are thus only six cases out of 36 in which there was no sign of any local lesion. And when we consider the very large part of the colon which cannot be examined it seems at least probable that there was a definite lesion in that part which could not be examined.

Treatment.—The most important factor in the treatment of colitis is undoubtedly to ascertain first of all the real cause of the condition. And the reason the treatment of colitis has often in the past been unsatisfactory is undoubtedly to be assigned to inaccurate diagnosis and treating as a disease what is only a symptom. In the inflammatory conditions rest in bed is advisable at the commencement of treatment. This is more particularly of value in enabling the patient to be kept under close observation. Irrigation of the bowel seems to be the best method of treatment if carried out properly and the inflammatory condition, as a rule, quickly subsides. A skilled nurse who understands how to get the irrigating fluid right up into the colon is essential. The irrigation must be done with a douche and not with a syringe. The reservoir should never be raised more than a foot or two feet above the anus and the fluid must be admitted slowly, with the patient in the semi-prone position. If the condition is at all acute it is better not to begin with irritant injections; an alkaline lotion, such as glycerine thymol co. 15 per cent., or sodium bicarbonate one drachm to the pint is very good, or if there is much ulceration hydrogen peroxide. Later argyrol 1 per cent., or potassium permanganate 1 in 2000, is very useful. Large injections of olive oil carefully administered and retained for as long as possible I have found most useful in some of the ulcerated cases. Irrigations are, however, quite useless unless care is taken to see that they reach the affected area, by no means always an easy matter. In some cases where there is local ulceration the ulcers can be painted with nitrate of silver or ichthyol through the sigmoidoscope. Dieting is also very important and the great thing is to get the bowels to act normally. Von Noorden's diet seems the best in most cases.

The most difficult cases to treat would seem to be those in which there is hypertrophic catarrh. They are easily made better but not easily cured. Stimulating injections are of the most value in these cases and treatment must be continued for some time. In the malignant cases operation is, of course, indicated where possible. In those cases where colitis is associated with a thickened and tender appendix, removal of the appendix, so as to get rid of a source of infection, is certainly indicated. In some of the cases of severe ulcerative colitis giving rest to the bowel by establishing a temporary artificial anus may be necessary, but I do not think this will often be the case if the local treatment of the colon by irrigations and applications through the sigmoidoscope is carefully carried out. Before a left inguinal colotomy is performed for colitis a careful examination with the sigmoidoscope should always be made to ascertain whether it is possible to open the bowel above the diseased area. The only advantage of appendicostomy seems to be that it enables the patient readily to perform irrigation of the colon for himself.

In those cases of colitis in which no local cause can be found to account for the symptoms and in which no material improvement in the symptoms has followed a careful and thorough course of medical treatment, I think surgical interference is indicated. Laparotomy should be performed and a thorough examination made of the large intestine; any adhesions which may be found binding down the bowel should be divided; if the sigmoid mesentery is unduly lax, allowing partial volvulus to occur, it should be shortened by stitching. If there is a retroflexed uterus it should be fixed in the normal position and if any thickening or ulceration of the bowel wall can be detected the advisability of resecting that portion of the bowel or of short-circuiting it must be considered.

I do not think that the operation of ileo-sigmoidostomy is advisable except in a few exceptional cases. When very extensive adhesions or ulcerations in the large bowel are discovered, which it does not seem probable can be permanently remedied, this operation should be considered, as it may be the only means of saving the patient from becoming a chronic invalid. It is not an operation, however, to be lightly performed, as the large intestine is a useful and necessary portion of the human body and not, as some people suppose, a useless cesspool, to be cut out or short-circuited without damage to its owner.

I am well aware that it may be said of my cases and observations that owing to the fact that I am a surgeon those cases of colitis in which a local cause is demonstrable tend to preponderate unduly. I admit that this is so, but it may equally well be said that the reverse occurs with those cases coming under the care of the physician. A very large number of cases with symptoms of colitis present themselves for treatment at St. Mark's Hospital and we thus have exceptional opportunities of observing such cases at that institution.

SACRO-COCCYGEAL TERATOID TUMOUR WITH FORMATION OF METASTASES IN THE GROIN.[1]

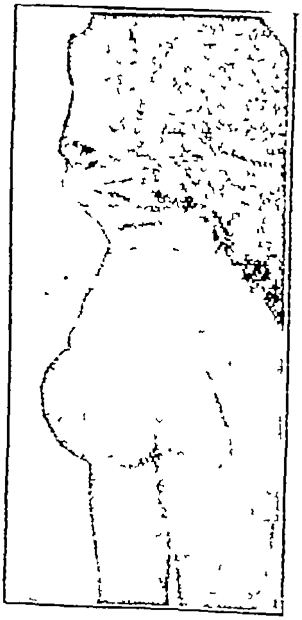
BY SETON PRINGLE, M.B. DUB., F.R.C.S. IREL.,
SURGEON TO MERCER'S HOSPITAL, DUBLIN.

As tumours of the sacro-coccygeal region may be classed among the surgical and pathological curiosities I considered the following case worthy of record, more especially as it presented some unusual features.

The patient, aged 57 years, was admitted to Mercer's Hospital, Dublin, on Sept. 23rd, 1904, having been sent up from the country to have a tumour removed which, as he said, "prevented him sitting down." His history was briefly as follows: 35 years previously he first noticed a small lump of about the size of a nut in the middle line some distance behind the anus. This tumour grew very slowly and remained quite painless until about four years ago, at that time being of the size of an orange, when it assumed more rapid growth, and he felt what he called "rheumatic pains" in it. Since then growth had proceeded in rather a peculiar manner; one part would, he said, grow rapidly, forming a painful nodule with the skin over it reddened, but when the nodule reached the size of a hen's egg growth would cease and the skin become pale again; then another part would take on growth and the process repeat itself. For the last few months the upper extremity had been growing rapidly in this manner. At no period did the tumour break down or ulcerate and it was freely moveable for years but had become more fixed in the last 12 months. Some 33 years ago, or two years after the appearance of the above-mentioned tumour, he noticed a small hard lump in his right groin which had continued to grow slowly and quite painlessly up to the time under notice when it was of about the size of a duck's egg. About 20 years ago he discovered another lump also in the right groin above and outside the earlier one and this was about the same size as its neighbour. For the last year he had noticed increasing difficulty in micturition and defæcation, the stools becoming smaller until they were about as thick as his index finger. He said that latterly he had suffered from "rheumatic pains" in his right hip and down the thigh to the knee but that otherwise he was quite strong, had not lost much weight, and his chief complaints were that he was unable to sit for any length of time and that pressure or cold caused pain in the lump. He knew of no relatives who had suffered from similar tumours, and his own children, the youngest being 20 years old, showed no abnormality.

On examination a large tumour was found over the sacral region, the general character of which can be well seen in the accompanying illustration (Fig. 1.) It measured 15 inches over all from the upper to the lower extremity and 11 inches from side to side, the base extending from the upper border of the sacrum to the anal margin and from slightly outside the left margin of the sacrum to well on to the right gluteal region. Its surface showed irregular lobulations; the skin over most of the mass was mottled blue but over the upper pole it was red and inflamed. There was no induration round the base and the adjacent skin appeared perfectly normal. On palpation the tumour was found to be more or less fixed apparently to the back of the sacrum, but it could be moved to a certain extent from side to side. The skin covering it could not be moved apart from the tumour, but this appeared to be due to its tightly stretched condition. The consistence of the growth was not uniform, most parts being

FIG. 1.



The sacro-coccygeal teratoma before removal.

---

[1] A paper read before the Pathological Section of the Royal Academy of Medicine in Ireland on March 15th, 1907.

densely hard, but over several small areas it was diffluent or semi-fluctuant and on one spot a fine crackling rather like that felt in chondromata could be elicited on deep pressure. The upper pole was rather softer than the rest of the mass and pressure here caused pain. In the right groin were two tumours, each of about the size of a large duck's egg, and evidently enlarged lymphatic glands. The skin over them was perfectly normal and freely moveable. These tumours felt very hard and firm with a slightly nodular surface; they were almost painless on pressure and were freely moveable.

On rectal examination the hollow of the sacrum was found to be full of a hard mass of growth which pushed forwards the posterior wall of the gut, so that the lumen was semilunar in outline. This mass extended up as high as the finger could reach; its surface was slightly nodular and pressure caused little pain. A hard mass could also be felt anteriorly around the prostate, and on passing a urethral sound an obstruction was found in the deep urethra through which a No. 6 English sound could just be passed.

From the examination it was evident that the growth was so far advanced that it was out of the question to attempt complete removal, but as the patient was extremely anxious to have something done I removed the glands from his right groin on Sept. 29th as a preliminary measure and for purposes of examination. They both shelled out quite easily and with little hæmorrhage, and the wound healed by first intention.

Description of the glands after removal.—Each gland was of about the size of a duck's egg, hard and firm to the touch, and rather nodular on the surface. Macroscopically the cut surface showed that a definite capsule inclosed the gland which was composed of lobulated masses varying in size from that of a pin's head to that of a nut and of different shades of a brownish-red colour. These nodules were separated from one another by bands of semi-transparent homogeneous material from which exuded a slimy mucus-like substance. Small hæmorrhages could be seen in parts. Microscopically it was seen that the lobulated masses were in reality cysts with connective-tissue walls. In these cysts could be seen three different appearances:—

1. Parts where the cyst was full of cells with oval nuclei, and running through the mass of cells were connective-tissue bands containing blood-vessels; these bands were evidently the cores of intracystic papillary outgrowths. The layer of cells next the core was in places distinctly cubical. The connective tissue in parts showed commencing mucoid change.

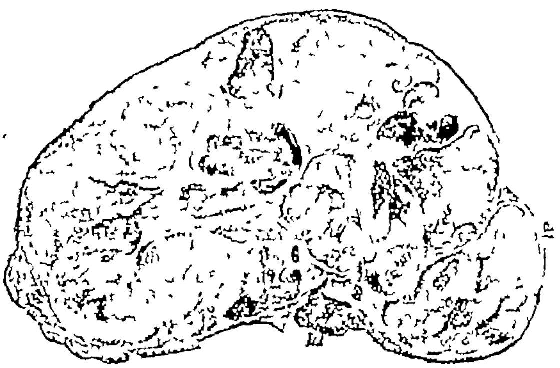
2. Parts where the cells were much less numerous and were arranged two or three rows deep round capillaries but separated from them by a zone of mucoid material. The cells abutting on this mucoid zone were distinctly columnar.

3. Parts where practically the whole tissue had been converted into mucoid. In places the capillaries could still be seen surrounded by a zone of mucoid, the different areas of mucoid being separated by a single layer of flattened spindle-shaped cells.

I take it that these three appearances are merely different stages of a very extensive mucoid change taking place in the connective-tissue stroma of the tumour round the blood-vessels and that this degeneration went on to such a degree that the cells atrophied from pressure and lessened blood-supply, and this reading, I think, explains the slow, almost inappreciable, growth of the glands. From these appearances we concluded that, although the tumour was malignant, it was of very slow growth and degenerated very quickly, so after explaining to the patient that he could not be permanently cured but only made more comfortable, I operated on Oct. 10th. It was found quite easy to remove the growth by cutting through only healthy tissue except at one part where a pedicle of about one and a half inches in diameter led into the pelvis through the coccyx which had been almost completely destroyed. The hæmorrhage was easily controlled by deep catgut sutures passed through muscles and fasciæ, drawing these structures together over the bared sacrum. As much of the intra-pelvic growth as possible was removed through the space left by the pedicle, a gauze drain was inserted, and the wound was closed by a continuous suture. There was considerable tension of the upper part of the wound and here the edges sloughed, but the wound rapidly granulated up. The patient was out of bed in a fortnight and a month later the wound was completely healed except for a small sinus over the position of the pedicle which ran into the pelvis. I then allowed him to return home as he could sit comfortably for an hour or two and expressed himself as very gratified with the result of the operation. Some time after his return to the country I heard that he had had several attacks of retention of urine and subacute obstruction of the bowel which prevented him regaining his strength. His condition gradually grew worse and he died 14 months after the operation. For the last few months he led a catheter life and had recourse to strong purgatives and enemata to empty the rectum.

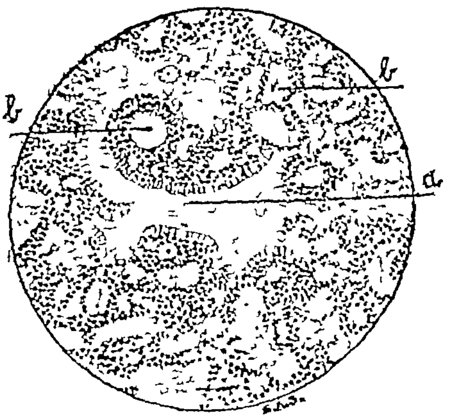
Description of the tumour.—Its weight was 3 pounds 13 ounces. The surface was lobulated as described above; the skin over it was in parts adherent and in other parts it could with little difficulty be peeled off, as could also the piece of gluteal muscle which I removed with the tumour at its base. The consistence was in most places densely hard, but the diffluent areas mentioned could also be made out. On section (see Fig. 2) the cut surface presented for the most part a white semi-transparent homogeneous or fibrillated appearance and from it exuded a great quantity of the same mucoid material as from the glands. This whitish structure was arranged irregularly in bands and masses throughout the tumour, comprising about three-fourths of the entire growth and felt hard and firm. The remainder of the tumour was composed of cysts of various sizes and shapes, as a rule inclosed by a definite fibrillated whitish wall and full of rather soft spongy material of all colours from a yellow to a dark red, almost black, colour, but in most places of a brownish-red shade.

FIG. 2.



Macroscopical appearance of tumour cut vertically. *a*, Upper pole. *b*, Pedicle cut across. (Scale ¼.)

FIG. 3.



Microscopical appearance of teratoma showing (*a*) connective-tissue core of intracystic process with layer of columnar cells; and (*b*) numerous capillaries surrounded by zone of mucoid material.

Microscopically the greater part of the tumour—i.e., the solid whitish parts described above—consisted of fibrous tissue generally hyaline in character, arranged in loose bundles separated by mucoid material; in places hæmorrhage had occurred into the loose fibrous tissue. The cystic parts of the growth were all of essentially the same structure and I will only describe the appearance seen in sections of the pedicle and the upper pole. Under low powers the section of the pedicle reminds one in general arrangement of the structure of papillary cystadenoma of the ovary. The interior of the cysts is broken up by numerous bands of connective tissue of varying strength, which acts as supports for the cellular elements of the tissue. In places these bands can be seen springing from the wall of the cyst, so that they are in reality the connective-tissue cores of the papillary outgrowths. Under higher powers the minute structure is seen to be almost identical with that described in the lymph glands—i.e., capillary vessels surrounded by fibrous tissue which in many places has become mucoid, and outside this two or three layers of epithelial cells, the layer next the fibrous tissue being columnar, while those outside this are irregular in shape and arrangement (see Fig. 3). In one place the appearance strongly resembles that seen in papilloma of the intestine. There are numerous pigmented cells in the connective-tissue stroma. The section of the upper pole or rapidly growing part of the tumour shows practically the same appearances. In a general survey we are again reminded of papillary cystadenoma of the ovary, though perhaps not so strongly. We see, again, the same essential structure of blood-vessels surrounded by fibrous tissue or mucoid substance, this surrounded by several layers of cells, the deep layer again columnar, the other irregular; the cells in their turn inclosing small irregular cyst spaces. In no part of the tumour is there evidence of marked mitosis and neither cartilage nor bone could be demonstrated, but a number of pigmented cells, perhaps of nervous origin, were seen.

The literature in English on sacro-coccygeal tumours is very scanty and the only reference of any value which I could find was in Bland-Sutton's "Tumours Innocent and Malignant." There he describes what he calls "congenital cystic sacroma," and considers that they arise from the post-anal gut. These tumours have, he says, a definite structure consisting of "closed vesicles lined with glandular epithelium and containing glue-like fluid. Many of these tumours are composed of cysts and duct-like passages lined with cubical epithelium held together by richly cellular connective tissue. In many situations the epithelium is columnar set upon flatter cubical cells. The cysts are filled with ropy mucus and vary in size from a nutshell to the smallest space visible to the naked eye. Many contain intracystic processes."

The German literature is, however, more profuse. Borst,[2] in dealing with teratomata of the anterior and posterior ends of the trunk, after describing the various forms of meningocele and tumours arising in connexion with meningocele or spinæ bifidæ, classifies the remaining teratomata of these regions into (*a*) tumours arising from fœtal inclusions—i.e., bigerminal tumours, and (*b*) monogerminal teratoid tumours, the essential difference being that in the former recognisable rudiments of organs not normally formed from the hind end of the fœtus are found. Tumours of either class occur commonly in the sacral and coccygeal region situated either in front or behind the vertebræ or in both places, the communication between the dorsal and ventral tumour then being either through or round the side of the bone. The structure in either case is also very similar, with the one essential difference mentioned above. Both consist of solid and cystic parts. In the solid part all forms of connective tissue are found with also usually fat, unstriped muscle, bone, cartilages, and nervous elements. The cysts vary in structure; they may be lined with a cubical, cylindrical, or flat epithelium or have a mucous membrane-like or ectodermic lining. Occasionally intestinal or neural canal epithelium is met with. True dermoid elements may also be found in some, while the contents of these cysts may be fatty, gelatinous, mucoid, or bloody, and their walls fibrous, cartilaginous, bony, muscular, pigmented, or papilliform. These various forms of cysts may be intermixed in the one tumour. Besides cysts we may find complex glandular structures and in a tumour reported by Middledorf[3] belonging to the second class a piece of well-formed intestine presumably derived from the post-anal gut was found. Hennig[4] published a paper on the congenital sacral tumours in which he gives an analysis of 22 cases collected from the literature and adds two of his own. Following von Bergmann he classifies tumours of this region which do not communicate with the spinal canal into (1) cysto-cavernous lymphangiomata and (2) teratomata; these latter he subdivides into (*a*) simple dermoids, (*b*) compound dermoids, (*c*) cysto-sarcomata, and (*d*) fœtal inclusions. His cysto-sarcomata are evidently identical with Borst's monogerminal teratoid tumours and with Bland-Sutton's tumours of the post-anal gut.

The theories of the origin of these tumours are various. Meckel regarded them as showing a tendency of the hind end of the embryo to develop like the fore end, Luschka as tumours of the coccygeal gland, Calbet, Hennig, and others as true parasitic double formations, while Borst looks on them as derived from vestigial and maldeveloped structures found normally at the hind end—viz., post-anal gut, neurenteric canal, aborted tail, and coccygeal remnant of the neural canal, and he considers that they arise from one or all of these.

I think there cannot be any doubt that the tumour which I have described above belongs to the class of monogerminal teratoid tumours, but it differs from all recorded cases because of the following peculiarities.

1. Its late appearance. Most recorded tumours have been present at birth and the others were discovered very soon after birth. Probably the intrapelvic portion of this tumour was present at birth and caused no symptoms, or perhaps a very small external sacral tumour existed long before it was noticed by the patient.

2. Its comparatively simple structure. This, however, may not be so simple as it appears, for although I made a careful search for bone, &c., and cut many pieces of the growth, still the examination cannot be considered complete, especially as one man cut over 400 sections of his tumour.

3. The occurrence of metastases in the groin. In the only other reported case with metastatic growth which I could discover the secondary deposit was found in the opposite ischio-rectal fossa. The patient was only five weeks old and died after operation, whereas in my case the metastases had been present for 33 and 20 years respectively.

In conclusion, I desire to thank Professor A. C. O'Sullivan for his interest in the case and to express my great indebtedness to Dr. T. G. Moorehead for his help with the literature, without which I fear my report of the case would have been incomplete.

Dublin.

NOTES OF A CASE IN WHICH GLYCOSURIA, DEPENDING UPON CHOLECYSTITIS AND CHOLANGITIS, DISAPPEARED AFTER DRAINAGE OF THE BILE DUCTS.

BY C. W. MANSELL MOULLIN, M.D. OXON., F.R.C.S. ENG.,
SENIOR SURGEON AND LECTURER ON SURGERY AT THE LONDON HOSPITAL.

THE following case, for the notes of which I am indebted to my house surgeon, Mr. A. J. Walton, is of especial interest at the present time in connexion with the surgical treatment of affections of the pancreas. It illustrates the fact almost as clearly as if it had been an experiment devised for the purpose, that in some instances glycosuria can be caused by septic infection of the pancreatic duct, extending into it from the common duct, and that the sugar will disappear from the urine completely after efficient drainage.

The patient, a stout, middle-aged woman, with an enormous flabby abdomen, was admitted into the London Hospital on April 4th last, with the diagnosis of calculous cholecystitis and cholangitis. There was a history of her having had an attack of biliary colic 11 years before and of her having been an in-patient under the care of my colleague, Dr. Percy Kidd, in October, 1906. On that occasion she was admitted for jaundice, which had already lasted several weeks, and which slowly disappeared under treatment. She does not appear at that time to have had any biliary colic, the only pain of which she complained being some dyspeptic trouble after food; and there was no vomiting after the first few days. The urine was examined on many occasions. No mention was made of any sugar having been present, and as the highest specific gravity was only 1032 it is not probable that there was any. The present illness began on April 2nd, suddenly, with severe pain in the abdomen and vomiting. The pain was of a dull aching character, not that of colic, and was felt chiefly on the left side of the abdomen in the epigastric region. It was made worse by taking food and was relieved by vomiting. Jaundice set in the day after the attack and was fairly deep. Sickness had been almost incessant. The bowels had not been opened since the beginning of her illness.

[3] Virchow's Archives, Band cl., p. 57.

[4] Ziegler's Beiträge, No. 28, p. 592.

On admission the patient was evidently very ill. The pulse was 96, intermitting every third beat, and very feeble. The temperature was 99·2° F. and the respirations were 28. The tongue was dry and red and there was deep jaundice. On examining the abdomen, which was very large and flabby, as if the patient had wasted a great deal of late, the edge of the liver could be felt some fingers' breadth below the margin of the ribs. The gall-bladder was enlarged and tender. It moved freely on respiration. The tenderness extended across the abdomen over the region of the pancreas, but nothing abnormal could be felt even on deep pressure. The urine was acid, dark brown in colour, was of specific gravity 1050, with an average of seven grammes of sugar in each 100 cubic centimetres. There was no albumin.

The patient's condition was such that immediate operation was out of the question. Calomel and sulphate of soda were given and the bowels were made to act by means of enemata, the motions being clay-coloured and very offensive. After some days the vomiting ceased, the patient was able to take liquid food, and the pain became less severe. The bile made its appearance in the fæces, the jaundice began to get lighter, and there was a definite change for the better, the pulse becoming fuller and less intermittent, though its frequency remained about the same. The temperature, however, which had fallen after the first two days, remained persistently below normal, and the amount of sugar in the urine and the specific gravity underwent no change.

Operation was performed on April 16th, the abdomen being opened by the usual incision through the right rectus. A calculus was felt low down in the common duct. With a little manipulation it was brought up to a part that was more accessible, the duct wall was incised, and the calculus was extracted. It proved to be a composite one of very irregular shape, made up of a number of small ones of pure cholesterin, more or less fused together, and coated over for the greater part of its surface by what appeared to be a kind of false membrane formed of lymph which adhered to it firmly. There were no other calculi in the duct and nothing abnormal could be felt in connexion with the pancreas. It was firm and hard but not to such an extent as to suggest any degree of chronic pancreatitis. The gall-bladder was full of small faceted calculi of the ordinary colour and composition, quite different from that which came from the common duct. A drainage-tube was fastened into the common duct, a second into the gall-bladder, and two long gauze drains were inserted, one in front of the common duct and the head of the pancreas, the other into the right renal pouch, and the abdomen was closed. The end of the bed was well raised and about five pints of saline solution with a little brandy were allowed to pass slowly into the rectum.

The after-history of the case needs very little comment. The gauze drains were left in for three and the tubes for 16 days. A very large amount of bile came away from the upper one in the gall-bladder; a much smaller quantity mixed with a cloudy watery fluid from the lower. The sinuses remained open for about a fortnight longer, all the bile passing with the motions, and then closed. On April 27th the specific gravity of the urine had fallen to 1035 and the amount of sugar to 2·6 grammes per 100 cubic centimetres. On May 4th it had fallen to 1018 and sugar was entirely absent. From that date until the time of the patient's discharge, although the urine was repeatedly examined, and she was on ordinary diet, there was no trace of sugar to be found.

The interest of this case lies in the disappearance of the glycosuria as soon as efficient drainage was established. From the repeated attacks of cholecystitis which the patient had had (there was a vague history of several others besides these two of which the dates were known), and from the fact that she had lost much weight (as much as 4 stones) in the past few years, it is probable that there was some degree of chronic pancreatitis, though the pancreas had not the stony hardness usually present in this condition. But the disease must have been merely of the interlobular type, and not as yet have involved the islands of Langerhans. Under the influence of septic inflammation spreading up the duct the interacinar portion of the gland became involved and glycosuria followed. Fortunately, as soon as a thorough drainage was established the inflammation subsided so quickly that to all appearance no permanent injury was inflicted upon the gland. Hitherto glycosuria, when occurring in association with cholecystitis and cholangitis, has been regarded as a bar to operation. As a matter of fact, it is one of the strongest arguments in favour of it. Thorough drainage not only prevents further injury being inflicted upon the gland by the septic organisms that have invaded it but, as in the above case, restores the gland to the condition in which it was before the septic invasion took place. So far as I am aware this is the first case in which a result of this kind has been recorded.

Wimpole-street, W.

MEDITATIONS ON GOUT.

(WRITTEN DURING AN ATTACK.)

BY CHARLES MERCIER, M.D. LOND., F.R.C.P. LOND.

IT is a disease of the rich, and of the wise also: so said the old physicians who had it themselves. On the first score I have no title to it, unless the saying refers to those riches which neither moth nor rust can corrupt, and which thieves cannot break through and steal. If this hypothesis is not sustainable, I can only suppose that, considering the severity of the attack, I must be endowed with a double and treble portion of wisdom. Kings, emperors, generals, admirals and philosophers are all said to be specially subject to gout; and, with respect to most of them, I am not in a position to deny it. The number of kings and emperors on my visiting list is quite limited; and, though my patients have comprised some admirals and more generals, it is not on account of gout that they have been my patients. But as to philosophers, I can speak more confidently. Among these, my acquaintance is extensive and varied, including the Socratic, the Platonic, the Aristotelian, the Kantian, the Hegelian (not so many of these lately, I am glad to say), the Comtian (almost extinct), and the Spencerian (a diminishing body). If there is, among all these, one who can endure an attack of gout, and still remain a philosopher, I do not know where to find him.

Scattered over the last half dozen years I have had about as many attacks of gout, which I thought at the time were pretty severe, but which I now know were trifling. However, they warned me; and since the first of them, that is to say, for the six years last past, I have lived the life of an anchorite; and adopted a diet which, if not quite "purin free," has been as nearly so as anyone who occasionally dines out can conveniently adhere to. Even on these social occasions, I am usually held in derision for my abstemiousness. Consequently, an attack of gout arouses in me a sense of injustice and injury quite distinct from the ill-temper which is commonly (and most untruly, I swear it!) said to accompany the malady.

The gout came on exactly one week after a particularly malignant attack of influenza, during the first two days of which the temperature was raised three or four degrees. Now, in fever, the metabolic processes are surely active in excess; and the amount of urates excreted is increased, so that one would expect an attack of fever to neutralise and prevent an attack of gout rather than to exacerbate it, if gout is due merely to an excess of urates in the blood.

During the whole of the attack of gout, the urine was copious, high coloured, and charged with abundance of urates; and no excess of purins was being ingested, but the contrary. Why, then, were urates deposited in the joints? The amount deposited, though enough to excite very severe inflammation, was but small compared with that which was being passed out through the kidneys. The kidneys were active, and were separating plenty, but—and this is most important—they were not acting up to their full capacity; for no deposit was thrown down as the urine cooled. The urine could, therefore, have held more in solution; and, as it does occasionally hold more in solution when warm than it can keep in solution when cold, it is clear that the kidneys, active and efficient as they were, were not acting up to their full capacity. The blood that supplied the toe was taken from the very same blood-stream that supplied the kidneys. That which supplied the kidneys was not supersaturated with urates, and yet urates were deposited in the toe. On other occasions, when deposition of urates from the cooling urine indicated that the urine, and therefore the blood, were supersaturated with urates, no urates were deposited in the toe. It seems difficult, in the face of these facts, to maintain that the deposition of urates in the joints is due to supersaturation of the blood with urates.

This, then, is the position:—The kidneys are acting freely and efficiently, yet, of the urate presented to them for excretion, while the greater part is excreted, a small portion is refused, and is carried on and deposited in the toe. Why is this? As it seems to me, there can be but one explanation, and that is, not that the blood was supersaturated, so that there was more urate in it than the kidneys were competent to deal with, but that this urate, that was carried on and deposited in the toe, existed in the blood in some combination which rendered it proof against the action of the kidney. In other words, gout depends, not on the quantity of uric acid in the blood, but on the fact that, of the uric acid in the blood, some portion is in a combination that renders it proof against the action of the kidney, and invests it with other qualities.

If gout is due to excess of uric acid in the blood, then gout should occur whenever the function of the kidney is impaired, so that the amount of urates excreted is much below normal. But gout is not an accompaniment of acute nephritis; nor is it an invariable accompaniment of the late stages of granular kidney. Kidney disease is a frequent accompaniment of gout, but it is by no means an invariable accompaniment, especially of early gout. Looking to the very great capacity that the kidney has of excreting urates, gout, if it is due to excess of urates in the blood, should never appear unless and until the kidneys are seriously diseased. But serious disease of the kidney is by no means necessary to gout. But if gout is due to some special combination of uric acid, which the kidneys try to excrete and fail to excrete, it is intelligible that the presentation of this substance to the kidney may have a damaging effect on the renal cells and that kidney disease should accompany late gout. On the other hand, it is not very intelligible that these cells should be damaged by dealing with the very substance which it is a principal part of their function to excrete.

My first hypothesis is, then, that gout is due to uric acid, but is not due to mere excess of uric acid. It is due, not to a quantitative, but to a qualitative alteration of the urates in the blood. It is owing to the presence of uric acid not as such, but of uric acid in some peculiar combination. This hypothesis is not antagonistic to any of the known facts concerning gout, and it is consistent with some which are inexplicable on the hypothesis of mere excess. Beer and champagne, neither of them rich in purins, will bring on gout much more often and much more rapidly than sweetbread, which owes nearly half its weight to purin. This is not intelligible if gout is due to quantitative excess of purin; but it is easily intelligible if beer and champagne provide some constituent which combines with even a small portion of the systemic uric acid to produce a noxious urate, while sweetbread, which introduces so much more purin into the circulation, introduces it in an innocuous form. The hypothesis harmonises also with the occasional precipitation of gout by mental fatigue, anxiety, and sorrow; for the effect of mental commotions in altering metabolism is indubitable, and among the products of such metabolic perturbance there may very well be small amounts of a substance that can combine with uric acid to form a noxious urate. But there is no evidence that the effect of mental commotion is to saturate the blood with uric acid, though such evidence should be obtainable if the fact were so. Again, migraine as well as gout is attributed to excess of uric acid in the blood. But migrainous headaches do not accompany attacks of gout, nor do attacks of gout accompany migraine. Migraine and gout do, it is true, often occur in the same person, but never at the same time. If they are both due to excess of uric acid in the blood, why do they not accompany each other? It may be said that if the excess of uric acid is deposited in the toe, it is no longer in the blood to produce migraine; but accepting this explanation, it still follows that an attack of gout should always be preceded by an attack of migraine, which should be relieved by the deposition of urate in the joint. But this is not what happens.

This leads me to my second hypothesis: that the combination of uric acid that produces gouty symptoms is not always the same, but there are probably many urates, which agree in being noxious, and in being more or less proof against separation by the kidney, but which differ in their pathological effects. There are many facts which favour this hypothesis. A patient of mine can always, by consuming a few heads of asparagus overnight, bring on a migrainous morning headache with scotoma—scotoma alone by a few heads, scotoma plus headache by a few more. Yet, however much asparagus he may consume, it never brings on an attack of gout. It is noteworthy also, that he gets neither scotoma nor headache by eating twice the weight of beef, although beef is said to contain ten grains of purin to the pound, while asparagus is credited with a grain and a half only. Clearly, therefore, something must be taken into account beyond the mere amount of purin that is consumed; and what is this something if not the particular chemical combination derived from the purin? Colchicum sometimes acts "as a specific" in gout; sometimes it produces no effect at all. I see no explanation of this difference except a difference in the chemical constitution of the urate. The attack of gout is, I take it, due to the deposition of urate in the joint. The subsidence of the attack follows, not the removal of the urate, for the joint continues to contain urate long after the attack is over, but to the cessation of deposition. If colchicum contributes to this cessation, it can only do so, as it seems to me, by entering into such a combination with the noxious urate in the blood that it ceases to be noxious, and becomes removable by renal action. If, as is the case, colchicum sometimes produces this effect and sometimes does not, it must be that in some cases the colchicum has a stronger affinity for uric acid than the body whose combination renders it noxious, and sometimes has a weaker affinity, and is unable therefore to displace this body. Hence I suggest that the varying manifestations of the gouty diathesis are due to varying, but allied, combinations of uric acid, probably with various but allied organic substances.

My third hypothesis concerns the attack of gout and its localisation in the joints. The prevalent explanation is that the deposition of the urate is due in some way to the fact that the tissues in which it is deposited are but slightly vascular; but if this is so, a favourite place for the deposition of the urate should be the cornea, in which such deposition is unknown. I suggest that the articular cartilages may secrete a substance which has a predominant power of breaking down the combination of uric acid with its organic ally, and converting it into urate of soda. On this view, the action of the cartilage, in breaking down the peccant combination, separating the urate from the blood, and retaining it in the joints, may be as conservative to the organism as a whole as the action of the blood cells in separating bacilli and consuming them. It is bad to have an attack of gout; but, by common consent, it is worse to have those gouty manifestations which cease when the attack of gout takes place. Surely, the recovery of the first Earl of Chatham from his insanity was cheaply purchased by an attack of gout. When a pernicious combination of uric acid is circulating in the blood, damaging the kidney, thickening the arterioles, perhaps perverting the action of the brain, it may be as valuable and as conservative for this combination to be broken down, even at the cost of a gouty joint, as it is to have a brood of streptococci extruded, even at the cost of an abscess. Almost monthly, discovery is made of some new and unsuspected chemical interaction of the tissues on one another and on the blood: there is nothing inherently improbable, then, in the suggestion that one of the functions of cartilage is to prepare a precipitant for some combinations of uric acid that are specially noxious, and that are proof against the separating action of the kidney. I am not chemist enough to know whether the resources of modern chemistry are equal to the task of testing these hypotheses, but should it be so, I suggest that they are a fair subject for bio-chemical investigation.

Wimpole-street, W.

EAST LONDON HOSPITAL FOR CHILDREN.—We learn that a bazaar to help this hospital is to be held in November next and that the Mayfair Motor Company of 22, Mortimer-street, London, W., has placed at the disposal of the chairman of the hospital one of its 6 horse power Mayfair cars. This is to be raffled for at the subscription price of £200, divided into 400 tickets of 10*s.* each, the money going to benefit the hospital. Tickets may be had either from the secretary of the hospital or from the secretary of the company, at whose offices the car will shortly be on show.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF MELÆNA NEONATORUM.

BY A. R. GUNN.

IN view of the appeal made by Dr. J. B. Page in the columns of THE LANCET of May 25th, p. 1431, the following instance of this rare and usually fatal condition may be worthy of record. One night last February I was present at a confinement in which labour was delayed by a persistent occipito-posterior presentation. The patient was also seen by Dr. H. Oliphant Nicholson. Forceps were applied and about 4 A.M. a small, under-sized, rather premature child was delivered, on whom vigorous and prolonged treatment was necessary before respiration could be induced. Some 20 hours after birth I was again called to the child who I found had passed during the three preceding hours, that is, since 9 P.M., several large, copious, extremely tarry stools, and had vomited frequently, and was at the time of my visit shrunken and collapsed. In the vomited material there were no clots, but it contained a small quantity of dark fluid blood which deeply stained the clothing. Since birth the child had not at any time been put to the breast. The treatment adopted was to give a small initial dose of castor oil followed by occasional sips of cold sterile water, strict attention being paid to the preservation of warmth. In a short time the vomiting ceased, the profuseness and tarry nature of the stools disappeared, and the child afterwards made an uneventful and wholly unexpected recovery.

Edinburgh.

A FATAL CASE OF MELÆNA NEONATORUM.

BY ALICE M. WHITE.

ON Jan. 11th, 1907, at 10.30 P.M., I was called in my capacity as a midwife to attend a confinement case. The notes may be interesting in connexion with the case reported by Dr. J. Basil Page in THE LANCET of May 25th, p. 1431. The mother had remained confined to her room for the last three months of her pregnancy owing to an injury. At 11.15 P.M. she was delivered of a female child and at 11.25 the placenta came away, the case being in all points normal and the female infant quite well. 36 hours after the birth I was called by an elder daughter, who said the baby was bleeding from the mouth. I was at the house within five minutes of the call and found no sign of bleeding from the mouth, but upon taking the child from the bed saw that she was lying in an actual pool of blood, which it appears the mother had not noticed. I at once dispatched the father for a medical man and undressed the child to find, if possible, the site of the hæmorrhage. This I found to be the rectum. By means of iron injections the hæmorrhage was controlled and the infant took a little diluted milk with a little salt added, but the case had gone too far and four hours later the child died. The medical man certified that she died from hæmorrhage and there was no post-mortem examination. The mother's story showed that the child had awakened at about 5 A.M. on the day of her death and had been given a few spoonsful of pure milk—contrary to directions, of course. She "changed" the child by candle light, early in the morning, and noticed that the motions were dark. I found on arrival that the child had passed large clots of blood, so the bleeding had evidently gone on for four or five hours, the mother having slept until 10 A.M. in the morning.

⁂ The interesting little accounts of cases of melæna neonatorum which we publish above are not written by medical practitioners. We very rarely publish in our clinical records the notes of any but qualified medical practitioners—we may say that we make this limitation a rule—and it is curious that the two exceptions to the rule should have occurred simultaneously. Miss White is a certified midwife. Mr. Gunn is a senior medical student working on "genetics" under Professor Schäfer in the physiological laboratory of the University of Edinburgh.—ED. L.

EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, E.

A CASE OF GENERAL PNEUMOCOCCAL INFECTION, WITH ACUTE NECROSIS OF BONE.

(Under the care of Dr. J. A. COUTTS.)

FOR the notes of the case we are indebted to Mr. A. L. Loughborough, house physician.

A female, aged two years, was admitted on April 3rd and died on May 8th, 1907. The history of the case was as follows. The child had always been healthy up to two months ago when she developed measles, since when she had not been herself. On April 1st (two days before admission) she had been taken suddenly ill with diarrhœa, vomiting, and fever. She had complained of headache and pain in the right side of her chest. Her breathing had been rapid and for the last two days she had developed an irritating and troublesome cough. There had been no convulsions. She had been lying semi-conscious in her mother's arms for the last 24 hours.

On admission the patient was a well-nourished child looking desperately ill; her face was ashen white. She was breathing rapidly and her alæ nasi were working. Respirations were laboured and accompanied now and then by a short dry cough. The respirations were 44, the pulse was 168, and the temperature was 102° F. As regards the lungs the right base was dull to percussion up to the angle of the scapula. On auscultation the breath sounds were diminished and bronchial in character; the voice sounds were distant. The left lung appeared to be normal. The heart's apex beat was a quarter of an inch outside the left nipple line. The sounds were clear, with some accentuation of the second at the base. There was no increase in the area of cardiac dulness. Physical examination revealed nothing further of interest. The right base was explored on admission with a negative result.

On the following day the child seemed much worse. The temperature was 103°, the pulse was 168, and the respirations were 68, and from this time the child went steadily down-hill. On the fourth day after admission she was practically moribund and was given a mustard pack with marked improvement to her condition. Two days later (the sixth after admission) a fluctuating and pulsating swelling of about the size of an ordinary hen's egg was noticed over the fourth and fifth spaces just outside the left nipple line. On closely examining this swelling the pulsation was clearly transmitted. The swelling was incised and about three ounces of greenish pus were evacuated. At first this was thought to be a pointing empyema, as air was sucked in and then expelled through the incision, but as no physical signs of a collection of fluid on this side were detected the incision was enlarged and a more complete examination revealed that the fifth rib at its junction with the cartilage had undergone necrosis and that the abscess formed was totally extrapleural. The bone was bare and quite easily removed, the wound being drained. As the signs at the right base persisted 14 days after admission and the child did not improve a second exploration was made and pus was found and evacuated by a simple incision and drainage. A few days later the right shoulder-joint was found to be swollen, painful, and apparently full of fluid, and this by exploration was found to be pus; the joint was accordingly opened and drained. Three days after this the left hip-joint obviously contained fluid which proved to be purulent. This joint was also opened and drained. From this time the child seemed to become gradually worse, getting more wasted every day, the temperature dropping to subnormal, and she died in an exhausted condition on May 8th.

Necropsy.—At the post-mortem examination it was found that about half an inch of the anterior end of the fifth rib, together with about the same amount of cartilage, had undergone acute necrosis with absorption. As regards the lungs the lower lobe on the right side was solid and airless (i.e., pneumonic); the left lower lobe was partially collapsed. The heart and pericardium were normal. An abscess was found between the pericardium and the pleura covering the right middle lobe. This abscess contained about three ounces of greenish non-offensive pus. The sinus of a granulating empyema was seen at the right base with much thickening of the pleura. The right shoulder-joint contained pus; the process had apparently started on the shaft side of the epiphysis, the head of the bone being completely separated. The left hip-joint also contained pus; the head of the bone was not separated; there was some erosion of cartilage. Nothing else of interest was found.

Bacteriology.—The following bacteriological examinations were made. Pus from the necrosed rib and from the empyema, the shoulder-joint, the hip-joint, and the pleuro-pericardial abscess (post mortem) gave pure cultures of the pneumococcus. Blood cultures ante-mortem and from the heart's blood post mortem proved negative.

Remarks by MR. LOUGHBOROUGH.—I think this case is of interest, as acute necrosis of bone due to the pneumococcus is so unusual that it is worthy of publication. The process of bone destruction with regard to the humerus is also peculiar. I should like to point out the marked good effect which the mustard pack (viz., a sheet wrung out in a solution of 1 pound of mustard to 3 pints of water, in which the child is wrapped from ten to 20 minutes, then washed in a warm bath and put into hot blankets) had on the child who was practically moribund at the time it was given.

For permission to publish these notes I am much indebted to Dr. Coutts. I also have to thank Dr. H. Pritchard for kindly giving me the post-mortem and bacteriological reports.

NORTHAMPTON GENERAL HOSPITAL.

A CASE OF LARGE PAPILLOMA OF THE OVARY.

(Under the care of Dr. W. M. ROBSON and Mr. P. N. B. ODGERS.)

A FEMALE, aged 26 years, unmarried, was admitted to the Northampton General Hospital under the care of Dr. Robson on June 24th, 1906 She gave the following history. For the last seven years she had been subject to attacks of pain in the lower part of the abdomen, which were always worse at the menstrual periods. These had never been bad enough to make her lie up until three weeks ago. The catamenia had been regular every four weeks, lasting usually four or five days, until three months ago, since when they had been irregular and scanty. She had always had some amount of dysmenorrhœa and this had got much worse during the last year. Her bowels had been constipated for some time; she had never had any trouble with micturition. Three weeks ago she had to take to her bed owing to the severity of the abdominal pain, and when first seen at this time by Dr. Robson in consultation with Dr. J. Bayley, she evidently had some pelvic peritonitis. The lower half of the abdomen did not move with respiration, while it was extremely rigid and tender. Her temperature was 101° F. Under appropriate treatment the acute symptoms subsided, and when admitted into the hospital a more thorough examination was possible.

On admission she was markedly anæmic and thin. On examination the lower part of the abdomen was filled with a large fixed irregular bossy mass which reached from the pubes almost to the umbilicus. Laterally it extended further to the left than to the right. A vaginal examination revealed the uterus pushed forwards by this mass which completely filled Douglas's pouch. The fundus of the anteverted uterus could be felt, pressed up against the abdominal wall, distinct from the tumour which was attached to its posterior aspect. There was no ascites. With regard to diagnosis, the two most likely conditions appeared to be either a tuberculous peritonitis originating in the tubes or a solid ovarian tumour, the former being favoured at all events at first. For two months, therefore, she was put out of doors and placed on forced feeding and cod-liver oil. Her general health improved greatly during this time but the pelvic condition remained unchanged.

An operation was now decided upon and this was performed by Mr. Odgers on August 21st. A median incision being made, a solid mass was at once exposed filling the pelvis and adherent to its lateral walls, to the posterior surface of the uterus, and to the pelvic colon. These adhesions were separated with some little difficulty and the tumour was then found to spring from the left ovary. This latter was removed with the left tube. The right ovary was normal and there was no evidence of secondary deposits on the general peritoneum. Although somewhat collapsed after the operation, the patient rallied well and her convalescence was uneventful. She left the hospital on Sept. 20th and since then has been back at work quite well.

The tumour, when removed, was of the size of a child's head and weighed 2½ pounds. While the greater portion of it presented smooth bosses and looked like a fibroma on section, the part near the ovary was papillary. The ovary itself was surrounded by, but not involved in, the papillomatous growth, which appeared to have its origin at the hilum. A piece of either portion of the tumour was sent to the Clinical Research Association, which reported that it was a simple papilloma throughout but presented differences in the amount of stroma present.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Causes and Surgical Treatment of Colitis.—Experiments on Prolonged Protein Feeding of Fowls and Rats.—Changes in the Red Corpuscles in Pulmonary Tuberculosis.

A MEETING of this society was held on June 11th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Mr. J. P. LOCKHART MUMMERY read a paper entitled "The Causes of Colitis, with Special Reference to its Surgical Treatment, with an Account of 36 Cases," which is published in full at p. 1633.—Dr. W. HALE WHITE, commenting on the title of the paper, remarked that the term colitis was too comprehensive, because this included many different intestinal conditions, whereas Mr. Mummery had apparently dealt with only one of these—namely, muco-membranous colitis. Membranous colitis, on the other hand, was a definite disease occurring for the most part (80 per cent.) in women, attended by the passage of mucous casts and frequently associated with neurotic symptoms, with various visceral displacements and sometimes with membranous dysmenorrhœa. Most of Mr. Mummery's cases were males, in only about one-third were mucous casts passed, and they did not fall into the latter category. It was undoubtedly important to recognise the existence of local lesions, and he (Dr. White) recognised the value of the sigmoidoscope, but there were many cases which were not dependent on a local lesion. Moreover, some cases were secondary to local trouble in other parts of the colon (as evidenced by tenderness and the length of the casts) which could not be so revealed. Undoubtedly, there was a large number of cases independent of any local lesion, cases which generally recovered under appropriate medical treatment.—Sir DYCE DUCKWORTH also regarded membranous colitis as a distinct class of the disease. Many of these cases got quite well when treated by diet and simple injections, and he instanced the results obtained at Plombières-les-Bains. Mr. Mummery's cases did not all belong to this group; they were, however, severe intractable cases suitable for surgical treatment.—Dr. F. PARKES WEBER referred to some of the minor forms of catarrhal colitis which were not included in Mr. Mummery's paper. Such minor forms were quite common and were amenable to exercises and various other forms of treatment. He (Dr. Weber) believed that many of these cases were diagnosed as cases of recurrent "biliousness." Subchloride of mercury was an excellent treatment for such cases, though not necessarily by its action on the liver. When the intestinal mucous membrane was unhealthy the flora of the intestine was increased and calomel might act as an antiseptic. Curiously, purgation aggravated the symptoms at first, probably by increased absorption of toxins from the bowel.—Dr. P. J. CAMMIDGE commented on the absence of blood from the fæces in the malignant cases recorded and asked if a chemical or microscopical examination had been made.

The presence of blood revealed in this way was, in his experience, a constant and diagnostic feature of malignant disease of the bowel. In regard to simple colitis he had found three constant features in the stools: (1) an alkaline reaction; (2) an excess of inorganic ash (as much as 40 per cent. of the dried fæces, compared with the normal 15 per cent.); and (3) disturbance of the normal ratio (10 to 12 per cent. of each) between the saponified and unsaponified fat, when this ratio might be represented by 8 per cent. of the former and 22 per cent. of the latter.—Dr. SYDNEY P. PHILIPS, discussing the causes of colitis, could not regard constipation alone as an adequate cause; it was a very common condition and existed in many people who never developed colitis. The causes of ulcerative and other forms of colitis were very obscure. The sigmoidoscope was doubtless useful but it could not render assistance when the lesion was above the sigmoid flexure, as in a case to which he referred of ulcer of the transverse colon.—Dr. H. A. CALEY believed that Mr. Mummery had regarded some of the lesions as causes which were in reality consequences of the colitis. Might not the ulcerations and the adhesions come under the latter category? In regard to appendicitis also Dr. Caley held that it was the result of a previous colitis and not the converse.—Mr. MUMMERY replied.

Dr. DAVID FORSYTH read a paper entitled "Experiments on Prolonged Protein Feeding, with Special Reference to the Thyroid Glands and the Osseous System," which will be published in an early issue of THE LANCET.

Dr. E. I. SPRIGGS exhibited three series of rats fed upon different diets. The first series was fed on meat and distilled water, the second on meat with lime salts, and the third (the control series) on bread and milk. The coats of the first series were rough and filthy, the animals were thin, and their general condition was bad. The coats of the second series were good and their general condition was healthy. The coats and health of the third series were normal. The conclusion was that the change observed in the fur of these animals when placed upon a proteid diet was due to the absence of lime salts rather than to the proteid diet.

A paper by Dr. NOEL D. BARDSWELL and Mr. J. E. CHAPMAN on the Changes in the Red Corpuscles in Pulmonary Tuberculosis was taken as read owing to insufficiency of time.

PATHOLOGICAL SOCIETY OF LONDON.

Hæmogregarines in Snakes.—The Histogenesis of Goitre.—Osteolipoma of the Brain.—Valedictory Address.

THE final meeting of this society was held on June 4th, Dr. P. H. PYE-SMITH, the President, being in the chair.

Dr. L. W. SAMBON described Ten New Hæmogregarines from the blood of as many species of snakes. The forms seen were considered to be sporonts, no division forms of the asexual cycle being observed. The sporonts were all encapsuled and the author pointed out that these capsules presented a delicate oblique line passing transversely across the long axis of the parasite at from 1 to 2 μ from one or both of its extremities. Sometimes this line showed as a white, highly refracting, unstained line, and in others, especially in specimens prepared with Giemsa's stain, these lines were stained of the same pinkish colour as the general outline of the capsule. It was suggested that these lines might represent lines of future cleavage of the capsule. In films prepared from blood which had been exposed to the air for a few minutes a greater or smaller number of sporonts were found free in the blood plasma. A small beak-like projection was noted at the anterior extremity of certain of the parasites. This small rostrum appeared to be retractile and in two species the author noted the frequent presence of a white somewhat sinuous line which, starting at the base of the rostrum, extended for about 7 μ into the interior of the parasite in a way which seemed to suggest a definite structure. In one species, *Hæmogregarina rarefaciens*, the sporonts presented a definite dimorphism which was thought to represent possibly sexual differentiation. The host cells of the same species appeared enlarged to two or three times their normal size while thinned out to an extraordinary degree, so that lines like creases ran across the corpuscles, the edges of which might appear wavy; such corpuscles were completely dehæmoglobinised. The species described were:—*Hæmogregarina Pococki*, in Indian python, Python molurus; *H. Shattocki*, in diamond snake, Python spilotes; *H. refringens*, in hoary snake, Pseudaspis cana; *H. Mansoni*, in testaceous snake, Zamenis flagilliformis; *H. rarefaciens*, in Couper's snake, Coluber corais; *H. Cantlici*, in conical eryx, Eryx conicus; *H. Wardi*, in king snake, Coronella getula; *H. Brendae*, in hissing sand snake, Psammophis sibilans; *H. Seligmanni*, in bushmaster, Lachesis mutus; and *H. Terzii*, in common boa, Boa constrictor.—Dr. D. N. NABARRO said that gregarines were known in the blood of other species—viz., frogs and fishes. These were sometimes found in the white corpuscles, and at the present time he had a rat in which the gregarines were present in the white corpuscles. He asked whether it was known what relation these bore to those found in the red corpuscles.—Dr. SAMBON, in reply, said that in snakes the leucocytes were also sometimes infected.

Dr. P. G. E. BAYON demonstrated a series of microscopical slides and specimens showing how Desquamation of the Epithelial Lining of the Colloid Follicles in the Thyroid may be followed by the Development of Parenchymatous Goitre. The new tissue grew from the existing follicular epithelium. Such desquamative processes had experimentally been shown to be the result of most varied causes, as injections of toxins or bacteria into the thyroid artery, ligature of the vessels, and injections of mineral poisons into the parenchyma of the gland. Increase in size of the gland had resulted in course of time. Some toxic reactions of the thyroid led up to proliferation of the secreting epithelium as found in Graves's disease and shown experimentally on the dog. Severe and diffuse injuries of the thyroid of bacterial or toxic origin led to complete connective tissue substitution of the glandular tissue, as seen in myxœdema and sporadic cretinism and produced experimentally in the rabbit and cat. Adenoma of the thyroid did not appear to take its departure from embryonal tissue, as its intracellular fat differentiated it from the cells of the embryo thyroid. Experimentally adenomatous tissue, with enormous increase in size of the thyroid, had been produced in the rabbit by incomplete ligature of the thyroid arteries. This was the first and only successful attempt to produce goitre experimentally in a non-goitrous district without the aid of bacterial infection.—Dr. W. P. HERRINGHAM said that the pathology suggested by Dr. Bayon was not supported by the clinical aspect of Graves's disease.—Dr. S. RUSSELL WELLS said that he had always regarded Graves's disease as a form of inflammation of the thyroid gland and had treated such cases with compresses of adrenalin with considerable success. He looked upon the condition as comparable to a scarlatinal nephritis.—Dr. C. G. SELIGMANN asked that since a severe lesion gave rise to a fibroid condition of the thyroid gland whether it could be shown that cretinism was due to the same process.—Dr. F. PARKES WEBER compared the condition met with in the thyroid to that found in the liver in which there was obstruction to the bile duct.—Dr. BAYON, in reply, said that there were two forms of cretinism: one in which the thyroid was never developed, only the parathyroid being present, and another in which the thyroid was fibrous.

Dr. F. PARKES WEBER and Mr. PETER PAUL DASER described an Osteo-lipoma of the Brain. A bean-shaped tumour, measuring 15 by 10 by 10 millimetres, was discovered at the base of the brain in making a post-mortem examination on a women, aged 29 years, with chronic renal and cardiac disease. It had produced no symptoms during life. It lay behind the optic chiasma and between the optic tracts, arising from the back of the infundibulum cerebri, close to the attachment of the pituitary body. It consisted of typical pale yellow fatty tissue, including a harder and darker nodule, of the size of a small pea, which on microscopic examination was found to be composed of cancellous bone. Sections cut after decalcification showed the structure of the trabeculæ to be that of true bone, with lacunæ and canaliculi and here and there an Haversian canal. The medullary spaces between the trabeculæ contained red bone marrow with scarcely any fat. In the literature on the subject an analogous case described by Dr. H. O. Bristowe at the society in 1855 was specially referred to.

The PRESIDENT then gave the following address. He said: Our society, which enters on a new career to-day, was founded in 1846. The first president was Dr. C. J. B. Williams, a pupil of Laennec, an accomplished pathologist and experimenter in more than one direction, a man of high character to whom I, as a young physician, was more than once indebted. He was followed, after two years, by a surgeon and this alternate choice between the two branches of the profession has been preserved until very recently. In 1848 Mr. Aston Key succeeded to the presidency; a brilliant surgeon, who was prematurely cut off by the epidemic cholera of 1850. His successor, Dr. Peter Mere Latham, was best known by his admirable lectures on medicine, almost equal in style to those of Paget and delivered at the same celebrated medical school. The second surgical president, Mr. Cæsar Hawkins of St. George's Hospital, died before he had completed his term (1853) and was followed by Dr. Guy Babington. This son of the eminent physician and mineralogist, whose statue stands in St. Paul's Cathedral, was also a remarkably accomplished man. He was sent to sea as a midshipman and was present at the battle of Copenhagen. He was afterwards professor of Tamil in India and graduated from Pembroke College, Cambridge—a learned physician and the physiologist who first defined the blood, not as consisting of serum and clot, but as of corpuscles and liquor sanguinis or plasma (as we now call it). He also invented a "glottiscope" in 1829 to enable the vocal cords to be seen, an earlier though less perfect instrument than those of Garcia (1855), and Türck (1857), and Czermak and Türck (1858). The name "speculum laryngis," or laryngoscope, was given by his colleague, Dr. Hodgkin. Babington was succeeded in 1855 by Moncrieff Arnott, a Scottish surgeon of wide scientific knowledge, which he used with liberality and ingenuity in practical hygiene. In 1857 Sir Thomas Watson became president, a man beloved and honoured like the elder Babington, and master of a style as classical and more easy than that of Latham. Sir William Fergusson, the eminent Scottish surgeon, of King's College, became president in 1859, and was succeeded by Dr. Copland, the author of a once popular cyclopædia of medicine. The next president was Sir Prescott Hewett, an accomplished surgeon and a most skilful operator. His successor in 1865, Dr. Peacock, was one of the best presidents we have ever had; a master of pathological anatomy, as well as of medicine, liberal and honourable, and not without a touch of humour on occasions. Like Fothergill, he was a member of the Society of Friends. He was followed by Sir John Simon (1867), senior surgeon, as Dr. Peacock was senior physician, of St. Thomas's Hospital. He was an able surgeon and a distinguished pathologist, but his general work was advising the Local Government Board on questions of public health, and his reports were remarkable for their scientific and practical value as well as for their precise and elaborate style, which sometimes reached eloquence. Sir Richard Quain was the next president; an Irishman, with the full share of his countrymen's ready wit and strenuous energy. His researches on fatty degeneration of the heart were of original value. He was the chief motive power in making the useful and necessary change from our original house in Berners-street to the present spacious rooms and he would have been delighted to see the union of societies which is now an accomplished fact. As President of the General Medical Council he gave a noble example of devotion to duty when knowing that he was the subject of incurable disease. The next surgical President was John Hilton (1871), an accomplished anatomist, an admirable teacher, and an original observer. His lectures on Rest and Pain were justly called by Giraldés "ce grand ouvrage de Mons. Hilton." A man no less eminent, upright, and plain-spoken was Sir William Jenner, for many years the Capo di Scuola at University College. He was a true pathologist and, as the acknowledged head of the profession, set a bright example of great talents used for the benefit of the public and the profession. Those of us who saw him introducing a deputation to the Home secretary, Sir Richard Cross, will never forget his eloquent defence of scientific investigation. The following President was Mr. George Pollock of St. George's Hospital, member of a family renowned in law and in arms, as well as in medicine, and himself a judicious and successful surgeon. Mr. Pollock was followed by Dr. Murchison (1877), a pupil of Hughes Bennett at Edinburgh, and long a remarkable bedside teacher at St. Thomas's Hospital, who, like Peacock, was removed by sudden death when visiting a patient. He was an eminent pathologist and an excellent geologist as well as a clinical teacher. The next president was Mr. Hulke, a sound surgeon, an accurate pathologist, and sharing with the elder Babington and Murchison the honour of eminence in geology, for Mr. Hulke was president of the Geological Society and of the College of Surgeons as well as of our society. Dr. Bristowe of St. Thomas's Hospital was a friend and colleague of Wilks, whom he rivalled in the number and value of his contributions to this society. He was an admirable teacher and a cultivated and liberal man. The majority has long received the next president on our list, Sir James Paget (1887), one of the most eminent pathologists this society can boast. All his observations were accurate and his exposition clear and concise. His insight was remarkable and wide. In purity of style and in oratory he outstripped all his fellows. His son's biography is a remarkable success in a difficult task. Sir George Humphry of Cambridge was an admirable lecturer, a keen observer, and a philosophical anatomist. The services he rendered to the Medical School at Cambridge deserve to be held in everlasting remembrance. Much more recently this society has been deprived by death of Sir John Burdon Sanderson, who became President in 1902—an eminent and accomplished pathologist who touched every allied subject and who adorned all that he touched. His work in University College and at Oxford has been well described by his successor, Professor Gotch. His lofty stature, his fine features, his dignity and urbanity, combined to form a figure of singular interest. As a teacher and a writer he was no less admirable. His best original work lay in that fruitful field which lies on the confines of zoology and botany. Such is the list of our past presidents who have joined the majority. But we thankfully and proudly point to no less distinguished men who are still with us. I could not do justice to their merits and must content myself with barely reciting the names of our surviving presidents: Sir Samuel Wilks, Mr. Hutchinson, Dr. Dickinson, Dr. Pavy, Mr. Butlin, Dr. Payne, and Mr. Watson Cheyne. May they long enjoy their well-earned reputation and rest assured that we regard them with pride and gratitude, with admiration and affection. When our society was founded pathology was still the handmaid of medicine and surgery, as is shown by the names I have cited. The science has now a far more independent position and is the foundation or *institute* on which all scientific prevention and treatment of diseases must rest. The study of morbid anatomy was the beginning of rational pathology. Then followed experiments on living animals, like those of Harvey himself, of Mayow, of Stephen Hales, of Hunter, and of Sir Charles Bell. Since 1846 we have seen the rise and vast progress of bacteriology as the third and most important chapter in the cause of disease. The fourth division of pathology is chemical, at present in its infancy, but probably destined to open many fresh paths to investigation. Especially fruitful will probably be the borderland between animal and vegetable pathology. The recent investigations by Professor Halliburton and Professor Mott into degeneration of nerve fibres deal with the conditions not only histological but also chemical. Moreover, by an unexpected series of observations it appears to be demonstrated that a parallel series of changes, after Wallerian degeneration of nerve fibres but in the reverse order, may lead to a restoration of the axis cylinder and ultimately of the whole injured nerve fibre. At present the future of experimental pathology lies on the knees of the Royal Commission on Vivisection. Let us hope that the result will be to give greater freedom for experimental methods. The minute anatomy of disease is not yet complete. The chemical aspect of pathology is not more than begun and our contributions in this department are comparatively few, though in value they have been great. Nowhere is the ground more promising than on the confines of physics and physiology, between botany and zoology, between chemistry and physics. The investigations embodied in Professor Farmer's admirable lecture before the Royal Society show how complicated may be the structure of a single cell. But complicated or simple it still baffles all attempts to explain its functions and their mechanism. To apply the words of an anonymous poet of the seventeenth century: In the ovum or the germ-cell

> "The thread of life untwisted is
> Into its first consistencies;
> Infant nature cradled here
> In its principles appear."

And, so untwisted, its principles are as great a puzzle as ever.

The society was then declared dissolved and the present council and officers were elected to constitute a provisional committee of the Pathological Section of the Royal Society of Medicine.

OBSTETRICAL SOCIETY OF LONDON.

Pregnancy in a Rudimentary Uterine Horn.—Primary Vaginal Embolic Chorion-epithelioma. — Chorion-epithelioma complicated by Hæmatometra.—Exhibition of Specimens.

A MEETING of this society was held on June 5th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. H. RUSSELL ANDREWS read a short communication on Two Cases of Pregnancy in a Rudimentary Uterine Horn. In the first case pregnancy had occurred in a right rudimentary horn and had gone on to about eight months when the fœtus died. Laparotomy was performed five months later, when suppuration had occurred. The specimen removed showed a small uterine cavity on the left side and the large right horn. The patient recovered. The second case was one of ruptured pregnancy through the rudimentary uterine horn at about the eighth month. The pregnant horn ruptured causing severe intra-peritoneal hæmorrhage. Laparotomy was performed and the pregnant horn removed but the patient died about an hour after the operation. The fœtus did not appear to be of much more than six months' development.—Miss L. GARRETT ANDERSON mentioned a case of cornual pregnancy on which she had operated recently. The gestation sac lay in the undeveloped right horn of the double uterus and corresponded to about two months pregnancy. The right ovary contained a recent corpus luteum. There was no communication between the right horn and the exterior.

Mr. HENRY T. HICKS read a paper on Primary Vaginal Embolic Chorion-epithelioma which was founded on a case of primary chorion-epithelioma occurring in the vagina of a women, aged 28 years. A hydatid mole was passed and the growth was accidentally discovered about a month later. There was no evidence of primary uterine growth. The sections showed that the growth had the structure of a chorion-epithelioma, but no villi were seen. 14 other cases had been collected from the literature on the subject and the question of the degree of malignancy of this form of growth was discussed, as well as the theories as to the origin of the vaginal growths. The time at which the growth might appear in relation to the gestation was also mentioned. The patient remained free from growth for seven months after removal of the first growth. The second growth was excised without delay but two new foci appeared quickly. These were removed but two months later the anterior vaginal wall became rapidly infiltrated with extensive growth and it was decided that further operation would be hopeless. The patient, who up to this time had been comparatively well, now went downhill with great rapidity. The growth commenced to fungate into the vagina in many places, causing hæmorrhage. The temperature rose and signs of pulmonary trouble became evident. The patient died on May 8th, 1907, 11 months after the passage of the mole. The specimen removed at the necropsy was shown, together with sections and drawings of the growth. Some secondary nodules were found in the right lung.

Dr. W. S. A. GRIFFITH and Dr. HERBERT WILLIAMSON communicated a paper on a case of Chorion-epithelioma complicated by Hæmatometra. The case was recorded of a woman, aged 42 years, who was delivered of a mole, probably hydatidiform, on Dec. 30th, 1905 The patient had borne four children, the last eight years previously; her fifth pregnancy commenced in the early part of June, 1905. From August to December she suffered from numerous small vaginal hæmorrhages; from Nov. 17th to Dec. 29th she was under close observation, and as no increase in the size of the uterus occurred during this period a diagnosis of molar pregnancy was made and abortion was induced. A mole was expelled which in its general characters resembled a carneous mole, but upon the surface were seen a few vesicles. Three week later (January, 1906) the patient suffered from persistent hæmorrhage and the passage of clots; the uterus was explored and a quantity of blood clot and débris was removed. From this time the hæmorrhage ceased excepting for the loss of a very small quantity of dark blood on Feb. 16th, but the uterus again became enlarged and pain was felt in the pelvis. On March 3rd the uterus and ovaries were removed by the abdominal route. In November, 1906, the patient died with signs of new growth in the lungs. The uterine cavity was greatly distended with fluid and clotted blood, the cervix being completely occluded by blood clot. A growth of the nature of a chorion-epithelioma were found on the anterior wall near the fundus. Numerous lutein cysts were present in both ovaries. A description of the naked-eye and microscopical appearances of the parts removed was given and special attention was drawn—(1) to the excessive formation and wide distribution of lutein tissues throughout the ovaries; (2) to the support afforded by the specimen to the theory that lutein cells might arise by modification of the connective-tissue cells of the ovarian stroma; and (3) to the presence of a layer of necrosed tissue closely resembling Nitabuch's layer of canalised fibrin between the uterine wall and tumour outgrowths.—Mr. J. H. TARGETT thought that all cases of double lutein cystic tumours of the ovary should be carefully recorded. At an operation for ovarian cyst with pregnancy at the fourth month he found that the tumour consisted of thin-walled lutein cysts which partly ruptured on removal. The opposite ovary was in a similar condition. Both tumours were removed. A fortnight later the patient aborted. The fœtus was macerated and the placenta was partly composed of vesicular mole. So far the patient had shown no sign of development of chorion-epithelioma —After some remarks by Dr. G. F. BLACKER, Mr. HICKS and Dr. GRIFFITH replied.

The following specimens were shown:—

Dr. C. J. N. LONGRIDGE: (1) Rupture of the Heart in a Still-born Baby; and (2) specimen and drawings of Dilated Ureters in Still-born Infants.

Dr. AMAND J. M. ROUTH: Pelvic Organs from a case considered to have Inoperable Ovarian Papilloma seven years previously.

The PRESIDENT: Myomatous Uterus, weighing 7 pounds, in a patient aged 22 years.

Dr. BRIGGS: Fibroid Induration around a Needle removed from the Left Labium Majus; (2) Early Tubal Pregnancy; and (3) Ovarian Pregnancy.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Lympho-sarcoma of the Lung.—Tuberculin Treatment of Tuberculosis.—Spleno-medullary Leukæmia.—Cerebellar-pontine Cyst.

A MEETING of this section was held on May 17th, Dr. T. P. C. KIRKPATRICK being in the chair.

Dr. JAMES CRAIG read notes on a case of Lympho-sarcoma of the Left Lung and exhibited the specimen. The patient was a man, aged 46 years, who came under Dr. Craig's care on March 12th, 1907. He had orthopnœa, cough, frothy expectoration, œdema of the lower limbs, slight ascites, albuminuria, and systolic aortic murmur. The left lung showed physical signs of complete solidification, with thickened pleura. He died on April 4th. The necropsy showed that a white, opaque, homogeneous, spherical tumour occupied the greater portion of the left lung. Secondary growths were present in the rim of lung tissue which the primary growth had not invaded. Portions of the tumour extended along the course of the left pulmonary veins, the pulmonary artery, and the aorta, so as to appear within the pericardium. The tumour appeared to have started in the bronchial glands and to have spread outwards.

Dr. FRANK J. DUNNE exhibited six cases of Tuberculosis treated by Professor Deny's Tuberculin in the South Dublin Union Hospital. One of the patients was a girl suffering from tuberculous disease of the wrist. The commencing dose of tuberculin administered to her was 5 parts in 1,000,000 and he did not know what would have happened if he had given her the dose of half a milligramme which is recommended in the case of Professor Robert Koch's tuberculin. Tuberculin at present had to be used with very great care and he believed that the ordinary trial doses were too strong. The cases were selected from one-third of the total (150) which he injected.

Dr. A. R PARSONS read a paper on a case of Spleno-medullary Leukæmia which had undergone a very remarkable improvement under treatment with arsenic—improvement both in the size of the spleen and the condition of the blood. In another patient, a woman, 55 years of age, who had been on arsenic for about five months, the treatment had produced diarrhœa and vomiting. She then came to him, and, as the arsenic had caused no improvement, he put her under the x rays. After 20 sittings the spleen commenced to diminish in size and there was also a marked diminution in the white corpuscles. The case therefore proved that the x rays alone could bring about a remarkable improvement.

Dr. HENRY O. DRURY cited the case of a woman who had a much larger spleen than the one described by Dr. Parsons. Every drug treatment was tried without result. Then they tried the x ray treatment alone and the spleen was enormously reduced. Ultimately she died from syncope.

Dr. G. PEACOCKE read notes of a case of Cerebellar-pontine Cyst which occurred in a man, aged 30 years. His symptoms were frontal headache, giddiness and staggering gait, failing sight, and deafness of the left ear. There was no vomiting. Examination showed paralysis of the muscles supplied by the seventh nerve on the left side and loss of sensation on the left side of the face. There was no loss of power or sensation in the legs or arms. The thoracic and abdominal organs were healthy. Examination of the eye showed optic neuritis, with small hæmorrhages and a white patch in the neighbourhood of the optic disc. There was no elevation of temperature and the pulse was normal. The patient died quite suddenly about six months after the first onset of symptoms. The necropsy showed a cystic growth involving both cerebellum and pons on the left side.

SECTION OF OBSTETRICS.

Exhibition of Specimens.—Discussion on the Report of the Rotunda Hospital.

A MEETING of this section was held on May 24th, Dr. R. D. PUREFOY, the President of the section, being in the chair.

Dr. HENRY JELLETT exhibited the following specimens: (1) A Uterus and Upper two-thirds of Vagina removed by Werder's method for cancer of the vagina; and (2) the remainder of the Vagina and the Inguinal Glands from the same case. He said that cancer of the vagina was a very rare condition. The patient was 39 years of age. She made a favourable recovery.—Mr. E. HASTINGS TWEEDY said that it appeared to him, from the description, to be a case of malignant disease of the vagina pure and simple; he was therefore anxious to know why Dr. Jellett considered the removal of the uterus necessary.

Dr. ROBERT J. ROWLETTE said that on first examining the vagina he had little doubt that he would find adeno-carcinoma of the body of the uterus, but on cutting the uterus and finding no primary focus of the disease he had, he thought, to conclude that it was primary in the vagina. It was possible that it was an adeno-carcinoma originating in Wolffian remains, or it might be an endothelioma.

Dr. JELLETT, in reply, said that the uterus was removed both because he believed the case to be one of intra-cervical carcinoma extending into the vagina, and because in any case of vaginal carcinoma, if the entire vagina had to be removed, it was necessary also to remove the uterus.

The adjourned discussion on the Report of the Rotunda Hospital for the Year 1905–06, by Mr. E. Hastings Tweedy, the master of the hospital, was then resumed.—Dr. JELLETT referred at some length to a case of concealed accidental hæmorrhage to which he had been called from the Rotunda Hospital some ten years before. He performed Porro's operation and found the placenta floating about in the uterus, which was full of blood. At a subsequent discussion his treatment was objected to on the ground that a large number of cases of concealed accidental hæmorrhage had been successfully treated by other means. If that were so, then Porro's operation was unjustifiable. Mr. Tweedy stated that the case in the report was the first case which he had ever seen and he (Dr. Jellett) had made out some statistics on the matter which showed that up to the year 1896 only five cases had occurred amongst 43,000 patients in the practice of the Rotunda Hospital. Mr. Tweedy's statement that such cases were of extreme rarity was therefore perfectly correct. Mr. Tweedy had a theory that a plug in the vagina would compress the uterine arteries; that theory was susceptible of proof, as if the uterine arteries were compressed the child would die, and that the child did not always die was proved by a case in Mr. Tweedy's present report. If a uterus from which no blood was escaping went on increasing in size he thought it was fallacious to suppose that a plug would make any difference, and the only thing that could be said for it was that it might bring on labour. He suggested that the condition was to all intents and purposes identical with that of internal hæmorrhage anywhere else, and consequently the correct treatment was to get to the bleeding point from above or from below and to stop the hæmorrhage at its point of origin.—Professor ALFRED J. SMITH regretted that he could find no advance in the teaching of midwifery in the report; he also regretted that methods of treatment were not set out in greater detail. As a teacher of students he would be glad to know why Mr. Tweedy altered the old-established division of ante-partum hæmorrhage. Again, he thought the results of the standard of morbidity were extremely notable. The Rotunda Hospital estimate made it a remarkably good standard, whereas the British Medical Association standard made it the same as last year. The question of which was the better standard was of importance to anyone estimating statistics. Then in the treatment of abortions it was not stated what kind of active interference was resorted to. He made the criticisms with a view to eliciting greater detail for the benefit of those who, like himself, would turn to it for information and enlightenment.—Sir WILLIAM J. SMYLY said that while he recognised the great difficulty in compiling tables, he agreed with Professor Smith as to the advisability of having more details in regard to interference in abortion, particularly as to the number of cases in which interference was necessary and the nature of the interference. He regarded the introduction of separate cots for infants as a matter of great importance.—Mr. J. SPENCER SHEILL said that it seemed to him peculiar that a patient in a healthy condition could die from labour collapse. The three cases referred to by Mr. Tweedy bore a strong resemblance to each other in respect of causation. He did not think that "shock" was the correct term. If the normal shock of labour acted on a patient in an unhealthy condition it was not the shock that was the primary cause of death. He thought that it would be better to put such cases down as death from unknown causes rather than under the ambiguous term of shock.—Mr. J. S. ASHE said he thought that they could greatly improve their methods of giving morphine salts. There were derivatives of morphine which were not so depressing as the hydrochloride.—The PRESIDENT expressed the opinion that pubiotomy would go a long way to rendering the induction of premature labour unfashionable, but he still thought that cases would be found for a while longer in circumstances which would justify induction.—Mr. HASTINGS TWEEDY, in reply, said that the point which Dr. Jellett had made in regard to concealed accidental hæmorrhage was a particularly good one. If he stopped the hæmorrhage in the uterine arteries the child died because he stopped the blood that went to the placenta, that was an apparently weak point in the theory; but he could say that he had never yet failed to stop hæmorrhage coming through a plug in the vagina, and he had never known of hæmorrhage pouring out over the plug. He had shown over and over again that there was no blood collected in the uterus when once the vagina was plugged. The plugging of the vagina caused a considerable amount of shock to the patient through pressing on the nerves, and he regretted to say that patients often did not get better in spite of the plugging of the vagina even though the hæmorrhage ceased, nor had he ever seen a living child born after plugging the vagina in the manner recommended as treatment for accidental hæmorrhage. As regards the cases of death from labour shock Mr. Sheill would see that Dr. Rowlette could find nothing to account for death, and though some other condition might have produced the shock it was the shock that killed the patient. Sometimes the retention of the placenta gave rise to profound shock quite apart from hæmorrhage.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—A meeting of this society was held on May 10th, Dr. R. H. Woods of Dublin, the President, being in the chair.—The President showed a case of Accidental Cut-throat which had healed in such a way that a cicatricial diaphragm had formed from the vertebræ to the epiglottis at the level of the hyoid bone, cutting off all communication between the nose, mouth, and pharynx above and the larynx and œsophagus below. Respiration and feeding had been carried on through an opening in the thyro-hyoid membrane. When first taken to Dr. Woods the patient had not spoken or breathed through her mouth for 15 months. The pharynx above the stricture held a pool of saliva, which could only be emptied by the patient holding her head forward and allowing the fluid to run out. The three difficulties, that of breathing, that of swallowing, and that of the saliva, were solved by dilating a pin-hole opening found in the diaphragm and so providing an air-way, feeding being carried out by a tube inserted into the gullet through the opening in the front of the neck, and the accumulation of saliva being got rid of by a specially constructed cannula which provided a breath-way, while a small "by-pass" connected with an air-pump was attached to the patient's belt, and supplied a means of getting rid of the annoyance experienced from the continual collection in the upper cul-de-sac.—Dr. J. Dundas Grant and Mr. J. Bark expressed their admiration of the exhibitor's ingenuity in solving the difficult problems presented by this case.—Mr. W. Stuart-Low showed a case of Frontal Sinusitis in a girl, a sufferer from epilepsy, in whom no fit had occurred since the operation of opening the sinus had been performed three months previously. At the operation the sinus had been found to be packed with mucous polypi. Both sinuses had been cleared out through one opening by breaking down the intersinusal septum.—Mr. W. J. Chichele Nourse read notes of a Fatal Case of Otitic Cerebral Abscess and Meningitis. The patient, a healthy man, aged 60 years, had suffered from ear-discharge for 12 months. Frequent and transient attacks of earache in the right ear preceded the onset of the fatal illness, which was marked by a rigor. Some days later headache, drowsiness, and delirium appeared. On admission to hospital the patient was semi-comatose. Examining with Siegle's speculum a large piece of cholesteatoma was aspirated from the attic. There was no optic neuritis. Two operations were performed for the relief of the patient's symptoms. At the first, a large temporo-sphenoidal abscess was drained through a fistulous opening in the roof of the mastoid antrum. At the second, the lateral sinus was exposed and examined and the temporo-sphenoidal lobe and the cerebellum were opened into through trephine openings, without, however, altering the course of the illness, which terminated fatally 11 days after the first rigor. The necropsy showed that death had been caused by purulent meningitis.—This being the last meeting of this association as an independent entity, Dr. Dundas Grant read an interesting paper reviewing the history of the society since its establishment in 1888.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on June 7th, Dr. Leonard P. Mark, the President, being in the chair.—Dr. A. W. Addinsell read a paper on Metritis, illustrated by lantern slides and photographs. The paper dealt more particularly with the morbid anatomy and pathology of those cases of metritis considered to be due to chronic infection, especially as a result of gonorrhœa. In the intractable cases marked by severe and exhausting hæmorrhage, hysterectomy was considered to be generally indicated.—The paper was discussed by the President, by Dr. J. A. Mansell Moullin, and by Dr. G. D. Robinson who referred to the good results obtained by curettage followed by the application to the cavity of the uterus of pure nitric acid.—Dr. D. Arthur read a paper on Some Aspects of X Ray Work, also illustrated by lantern slides, and spoke in detail of the diagnostic value of skiagraphy in thoracic diseases, insisting on the significance of difference between the diaphragmatic excursions on the two sides, as shown by the use of the screen, in those cases of early pulmonary tuberculosis in which no apical deposit could be demonstrated. Dr. Arthur also explained the method of taking ortho-diascopic tracings, and pointed out its extreme value in enabling the localisation of intra-thoracic conditions such as abscess or tumour. An interesting account was also given of the manner in which different positions were assumed by the heart in certain circumstances of disease.—A discussion followed, in which Dr. A. J. Rice Oxley and Mr. W. McAdam Eccles took part.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—The annual meeting of this society was held on May 30th, Dr. W. C. Chaffey, the President, being in the chair. For the ensuing year Mr. H. H. Taylor was elected President; Dr. Chaffey and Mr. J. Turton, Vice-Presidents; Dr. W. A. Hollis, treasurer; Dr. R. J. Ryle, honorary librarian; Dr. C. H. Benham, Dr. P. S. Eves, Dr. W. Watson Griffin, Dr. E. Hobhouse, Mr. R. F. Jowers, Dr. F. J. Paley, Dr. L. A. Parry, and Mr. H. Stott members of the council; and Dr. Walter Broadbent and Mr. W. A. Bowring, honorary secretaries.

Reviews and Notices of Books.

Metabolism and Practical Medicine. By Professor CARL VON NOORDEN of Vienna. Vol. I.: The Physiology of Metabolism, by ADOLF MAGNUS-LEVY (Berlin), pp. 452. Vol. II.: The Pathology of Metabolism, by VON NOORDEN, KRAUS, SCHMIDT, WEINTRAUD, MATTHES, and STRAUSS, pp. 525. (Vol. III. not yet received.) Issued under the editorship of I. WALKER HALL, M.D. Vict. London: William Heinemann. 1907. Price of the three volumes £2 12*s*. 6*d*. net.

THIS is a translation of the second edition of von Noorden's well-known "Text-book of Metabolism" with some additions to the German text and enlargement of the bibliography by the inclusion of recent English, American, and other papers. It may be said that until comparatively lately the scientific examination of the processes of metabolism was almost confined to German, French, and Italian investigators, but within the last 20 years English and American workers have contributed largely to this branch of scientific medicine.

Perhaps the scope of the first volume will be best understood by giving the titles of its main chapters: I., Foodstuffs; II., Digestion and Absorption; III., Fate of the Foodstuffs in the Tissues; and IV., Metabolism in Man under the following heads: Total Energy Exchange, Nitrogenous Metabolism, Influence of Muscular Work upon Metabolism, Influence of Sexual Processes, the Rôle of Water, Mineral Substances, and Metabolism in Old Age. The translation has been done by several workers, but surely A. "Oberndorfer," one of the translators, is a misprint for Oberdorfer. In Chapter I. we find (p. 3) the following: "The fats and proteins are partly vegetable and partly mineral"—mineral is obviously a mistake for animal. In the discussion on the constitution of the protein molecules, which differ so much amongst themselves, reference is made to the striking fact discovered by Fischer and his pupils that leucin occurs to the amount of from 20 to 29 per cent. in casein and globin, while tyrosin is at most from 1 to 4·5 per cent. In globin 10·96 per cent. consists of histidin.

The chapters on foodstuffs and digestion and absorption (pp. 64) give a general review of these subjects. More interesting, however, is the third chapter which deals with the fate of foods inside the body. It used to be taught that the "purpose" of the splitting up of protein in the intestine was to make it soluble and capable of being absorbed. Its "significance," however, is that it enables the albumin of the food to be changed into the albumin of the tissues, and as these two forms differ in both the number and the combination of their C-containing nuclei a more or less extensive preliminary decomposition is inevitable. The recent investigations show that it is not peptones and albumoses but the products of a more advanced splitting up of the protein molecule which are the "building stones" from which the proteins of the tissues are reconstructed. The reconstruction probably does not take place in the intestinal wall, as was supposed by Neumeister and Hofmeister, because this tissue alone caused peptone to vanish. Since Cohnheim has proved that the peptones vanish, not because they are built up, but because they are broken down, it is doubtful if the synthesis—as is the case with fats—takes place in the intestinal wall and the question arises, Are the tissue proteins built up from the fragments of the protein molecules in the blood by the various organs of the body? This supposition is by no means indispensable, for the organism is certainly able to convert specific proteins of the organs into other kinds and therefore would be able to build up organ-protein out of neutral protein present in the blood. This is the case in the growth of the present in the blood. This is the case in the growth of the sexual organs at the expense of the vanishing lateral muscles in the fasting salmon. Thus the organism is able to interchange the proteins of its tissues. On this view the intestine would hand on half-manufactured stuff made out of the raw material which it receives but the organs would perfect the work and produce the finished article.

When we come to the forces that decompose proteins in the animal body recent investigations have shown that in almost every organ there exist specific ferments which act on proteins and others on fats and carbohydrates. Salkowski was the first to recognise the intracellular operation of ferments like pepsin or trypsin—a process now known as "auto-digestion" or "autolysis." These ferments do not originate in the alimentary canal. Round this question hangs that of the splitting off of ammonia and urea formation. The view long held that fat comes from protein owing to "fatty degeneration" is a view that it seems must now be discarded. There is an excellent chapter on Uric Acid and Purin Bases, dealing with these bodies in their chemical and in their physiological and pathological relations. The metabolism of fats and carbohydrates is fully considered, but perhaps to the physician the discussion on acetone bodies will prove of interest owing to the frequent occurrence of these substances in certain diseases. In acetonuria the source of the acetone is not the carbohydrates. Many additional references to this subject will be found in Vol. II. When we come to the energy side of the problem we find many excellent chapters. Zuntz gives valuable hints as to cycling for invalids: "As the feeling of fatigue is much less in cycling for a given amount of work than it is in walking there is much greater danger of overstrain in the case of the former than in other forms of exercise. This is true for a healthy person and much more so for an individual suffering from cardiac or pulmonary disease." Medical men will be interested in the chapters on Gaseous Exchanges, more especially on the Therapeutic Applications of Oxygen (Vol. I., p. 257), and that on the Lower Limits of Protein Intake, which includes a survey of the recent experiments of Chittenden. The remarks on massage and metabolism will also be read with advantage: "The direct effect of massage has been extraordinarily over-estimated." The metabolism during pregnancy and lactation is very fully dealt with. Not the least interesting chapters are those on water, salts, and old age.

The second volume is one that will undoubtedly attract the attention of the practitioner of medicine. To show its scope and interest we mention its leading contents: Hunger and Chronic Starvation and Overfeeding (C. von Noorden, pp. 1–69), Fever and Infection (F. Kraus, pp. 90–167), Diseases of the Stomach and Intestines (A. Schmidt, pp. 169–211), Diseases of the Liver (W. Weintraud, pp. 229–96), Diseases of Respiration and Circulation (M. Matthes, pp. 304–39), Diseases of the Blood (H. Strauss, pp. 350–420), and Diseases of the Kidneys (C. von Noorden, pp. 433–510). This is really an account of metabolism of diseased conditions, such as gives the reader an insight into the secret processes going on under the most diverse conditions. The practitioner must not look for the treatment of the corresponding diseases, for of that there is none. The results set forth if carefully studied will give him an insight into the processes that are going on in his patients and will lead him to attach more importance to certain symptoms both from a diagnostic and prognostic point of view. Where all is so excellently well set forth it is difficult to select a chapter for comment. The one on Fever and Infection strikes us as particularly thoughtful and suggestive, and though the two subjects are allied yet different it is well that the resemblances and differences should be set forth. This chapter should be read by every practitioner of medicine.

We have said enough to show how attractive is the whole subject and how well it is set forth, with a wealth of detail both of physiological and of pathological facts. Indeed, teachers of physiology, as well as of pathology and medicine, would do well to study it carefully, for in the end what is the pathology of metabolism but a variation of physiological metabolism. No sharp line divides them. The literature is particularly copious, but we are struck by the fact that in some subjects the data given reach only to 1895 or even 1886. Another remark, and that is the paucity of references to English names. It may be that English and American writers have not worked at these subjects.

Dr. Walker Hall and his collaborators have done good service in presenting this work in its English garb. We wish it every success and we feel sure that those who read and study it will not only profit thereby but they will get new inspiration for the study of those diseases which they may be called on to treat. Such a work forms a true basis for the philosophic study of the over-active exchanges and the varied phenomena—both those of matter and energy—which accompany the metabolic processes in health and disease.

Tropical Medicine, with Special Reference to the West Indies, Central America, Hawaii, and the Philippines, including a General Consideration of Tropical Hygiene. By THOMAS W. JACKSON, M.D., Lecturer on Tropical Medicine, Jefferson Medical College, Philadelphia. With 106 Illustrations. London: Rebman, Limited. 1907. Pp. 536. Price 17s. net.

WE welcome this contribution to tropical medicine, coming as it does from America, for although the English, German, and French authorities have given us excellent text-books on the subject, we have had none up to the present time from America. The author in his preface draws attention to the claims of tropical medicine upon American interests and shows how, without volition on their part, the American people have become responsible for the government and education of millions of men and women in distant parts of the world, including in them the tropical regions.

He first gives a lucid introduction and a general consideration of tropical hygiene. Under this heading he notes the facts as regards personal cleanliness and here we regret to notice that he does not warn his readers against the use of the cold bath, which, in India at least, is a sure means of exciting congestion of the liver, so much so that cold water bathing is practically non-existent. The subject of appropriate and nourishing food and of suitable clothing is next considered, and here again we find no mention of the importance of a red lining to a helmet to ward off heat-stroke. Exercise, rest, and the avoidance of heat and exhaustion are then considered. The measures of protection against infection are fully entered into as regards water, food, clothing, contagion, and the bites of insects and vermin. The account of mosquitoes is full enough for all practical purposes.

The author proceeds to describe the various diseases met with in the tropics which he classifies under the three heads of (1) systemic diseases; (2) animal parasitic diseases; and (3) diseases of undetermined or uncertain causation, local and constitutional, and skin diseases. The first disease treated of is cholera; the account of the symptoms given is excellent. We note, however, that Dr. Jackson holds that leucocytosis or its absence has no diagnostic or prognostic value in the disease. This is quite contrary to what has been found in India, where, as pointed out by Major Leonard Rogers, I.M.S., leucocytosis has a significance in that, well marked as it is in the disease generally, it is most marked in the severest and most fatal cases. With regard to the treatment, his experience fully bears out the opinion of Mr. Haffkine on the value of inoculation. The author does not mention the evacuant plan of the late Sir George Johnson or allude to his lucid theory of collapse. Beri-beri is next dealt with, and the clear classification of Dr. Hamilton Wright, who has done so much good work with regard to this affection, is followed. The author thinks the ultimate cause is a microbic organism gaining entrance into the body usually by the alimentary tract but also by the inspired air or through a lesion of the skin. The convincing experiment instituted by Baron Takaki concerning one method of the causation of beri beri is detailed. In the treatment due attention is drawn to the management of the cardiac crises that are so likely to arise.

Plague is the next subject which is dealt with in this work. Here the recent reports of Professor W. J. R. Simpson are alluded to, as well as the important facts which these reports brought out. Attention is directed to the conveyance of infection by the healthy through the medium of infected clothing, whilst emphasis is placed on the part played by infected rats. The questions of serum therapy and of the treatment by large doses of carbolic acid, as instituted by Dr. J. C. Thomson, receive due attention. Dengue is then described and after this the important subject of tropical dysentery receives attention. With reference to amœbic dysentery, we are glad to see that the author does not give this title as synonymous with tropical dysentery for he shows that tropical also embraces bacterial dysentery. In the description of this form of the disease, otherwise fairly complete, we fail to find any account of Major Rogers's important post-mortem findings which certainly differ from those of bacterial dysentery in a remarkable manner. Dr. Jackson's opinion of the treatment of amœbic dysentery with massive doses of ipecacuanha is that it is of no value. In the consideration of the subject of amœbic abscess of the liver the author details Mr. J. Cantlie's valuable researches as regards the depth to which the trocar may puncture the organ without damage to the vena cava. In the section on bacillary dysentery Shiga's well-known researches are given. In the treatment of this form the author does not speak in favour of ipecacuanha but recommends the administration of salines with the use of intestinal antiseptics, thereby giving a fresh instance as to the manner in which the treatment of dysentery varies with the special locality in which the disease is rife.

Space forbids us to deal adequately with all the subjects mentioned in this valuable work. The chapter on leprosy is illustrated by some excellent drawings and we are glad to see Radcliffe Crocker's treatment with injections of sozoiodol —not bichloride as in the text—of mercury mentioned. The chapters on malarial and Malta fevers are both excellent; the latter is fully up to date, the facts concerning the part played by goat's milk being mentioned. Yellow fever, knowledge of the correct etiology of which disease we owe to the American physicians, is well described. The diseases due to animal parasites receive their due attention, as do those of undetermined or uncertain causation and skin diseases. We heartily congratulate the author on the production of this work.

High-Frequency Currents. By H. EVELYN CROOK, M.D., B.S. Lond., F.R.C.S. Eng., formerly Assistant in the Electro-therapeutical Department, West London Hospital, &c. London: Baillière, Tindall, and Cox. 1906. Pp. 206. Price 7*s.* 6*d.* net.

WE welcome this contribution to the study of high-frequency currents and we think that it may be said to be the best work on the subject by a British author up to the present. While the book is well arranged a good deal of the matter in the preliminary chapters might have been omitted, as it is a fair inference that the person about to study high-frequency phenomena is already conversant with the elementary principles of electricity. The work may be said to begin at the commencement of Chapter VIII., in which the author deals with the physical properties of high-frequency electricity. A separate chapter is devoted to each of various classes of phenomena and these are followed by two chapters describing the different methods by which this form of electricity is applied for purposes of treatment. In Part II. are seven chapters, each of which is devoted to the consideration of effects produced on the different systems of the body, as also on heat production and on micro-organisms. The author has carefully summarised in this section all the information so far available and it is expressed in a very lucid and concise manner and the same remark applies to Part III. which deals with therapeutic applications.

We must confess to a sense of disappointment in that the author has given so little of his own personal observations and experiences. As a matter of fact, the two most important of the three sections of the book are made up almost entirely of the experiences of other investigators and for this reason it is to be regarded as an excellent compilation rather than as an original contribution. At the same time the work is a valuable one and should be in the hands of everyone seriously interested in the subject.

LIBRARY TABLE.

The Practical Medicine Series. Comprising ten volumes on the year's progress in Medicine and Surgery. General Editor: GUSTAVUS P. HEAD, M.D. Vol. I.: General Medicine, edited by FRANK BILLINGS, M.S., M.D., and J. H. SALISBURY, A.M., M.D. Series 1907. Chicago: The Year-Book Publishers. (Sole Agents for United Kingdom: G. Gillies and Co., Glasgow.) Pp. 364. Price 5*s.* net. (Complete series of ten volumes per annum £2 2*s.* net).—The scope of this year-book is somewhat more ambitious than that of others of its class, as in the ten annual volumes not only do the chief new methods of treatment and diagnosis come under review but the editors also include a good deal of old teaching that has been recently re-stated; this plan has its own merits but it renders the task of selection more difficult. As an example, many will find fault with the judgment that helped to perpetuate the old fallacy that the limit of percussion dulness of a normal heart does not extend beyond the right margin of the sternum. The book, however, does contain some valuable information and has evidently been carefully compiled. We understand that general medicine will be further considered in a supplementary volume. The present one contains over 100 pages about tuberculosis, in which all the heads of that complex subject are touched upon; then follows a chapter on diseases of the respiratory system. Under Pneumonia there is an editorial note deprecating the attempt to abort the disease by drugs, *pace* the enormous doses of quinine and iron advocated by Galbraith on the next page; the vexed question of alcohol in the treatment of this disease receives no editorial verdict. Diseases of the heart and blood-vessels are treated in 120 pages and form a very useful section; interesting observations on cardiac dynamics, and on such rare conditions as Stokes-Adams disease are recorded. In this respect (p. 204) an unfortunate misprint reads "interarticular" for "interauricular" septum. The present interest in blood pressure finds adequate expression, and diseases of the blood are also noticed. Acute rheumatism is rightly classed amongst the general infections and Poynton's and Paine's experiments towards establishing the specific claims of the rheumatic diplococcus are recorded. The book concludes with an account of recent work on certain general disorders and on diseases of the kidney in which the significance of albuminuria and variations in the salts content of the urine are discussed by various authorities. Throughout the book quotation is made from a great variety of sources and it is one that the busy practitioner may well find of use in his practical work no less than in his education in recent theory.

Our Sons: Their Start in Life. Reprinted from *The Guardian*. Second edition. London: *The Guardian* Office. Pp. 122. Price 2s. 6d. net.—This is a useful little book containing a series of articles on schools, the universities, the navy, army, and civil services, the medical and legal professions, engineering, surveying, farming, "the City" occupations, and secretarial work, and also on the various callings open to women. It contains in a handy form information as to the various means of entering these professions, the cost of training for them, and a brief discussion of their advantages. In discussing medicine we think that the author would have done well to lay more stress on the advantages of every student at least trying for a medical degree. Some men certainly do not realise this fact until, for various reasons, it is too late for them to take a matriculation examination. The total expense for the five years for "education, examination fees, books, and instruments" is set down at about £230. To many this will seem a low figure but a brief computation assures us that it is not unreasonable, although £250 would be nearer the mark for most men. The London medical student will be pleased to hear that in the author's opinion it is necessary "to utter a word of protest against the common idea of his personality. At times he shows the exuberance of spirits which is not surprising or reprehensible at his time of life, but even then he does not forget that he is a gentleman. He works hard and steadily." There are brief notes on the profession of medicine and nursing as occupations for women.

Crutches to Help Cripple Children.—We have received from Messrs. Bemrose a copy of a publication issued by them, entitled "Crutches to Help Cripple Children." In a covering letter they state that it is sent at the request of the Lord Mayor of London in aid of his lordship's Cripples' Fund. They further ask us to draw attention to the publication and this we have great pleasure in doing, for the helping of cripple children is a most worthy object. Criticism of the writers and artists who have contributed to the publication is not necessary in this place. All kind-hearted people will be grateful to those who have so contributed. But on p. 47 we notice a flaming advertisement from the person who calls himself "Dr." Bodie. He now runs an Electric Drug Company and boasts of having cured "hundreds of hopeless cases of paralysis discharged from the leading London and provincial hospitals." This statement in itself should have been sufficient to prove to the advertisement manager of "Crutches to Help Cripple Children" that he was accepting the money of a quack and in so doing by no means serving the true interests of a publication intended to enlist sympathy for what is a most deserving charity.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In an article on exophthalmic goitre in the May number of this journal Sir J. Halliday Croom concludes that the influence of pregnancy on this disease is very uncertain but tends to aggravate it; nevertheless, the subjects of Graves's disease need not be precluded from marrying or from becoming pregnant. Incidentally he quotes the opinion of Dr. T. D. Luke that exophthalmic goitre is one of the most dangerous conditions for the administration of a general anæsthetic. Mr. George A. Peters discusses the treatment of gall-stones in the gall-bladder and cystic duct and the indications for the different methods of procedure, and Dr. J. Eason writes on phagocytosis of erythrocytes in paroxysmal hæmoglobinuria. Dr. Ian Struthers Stewart and Dr. C. L. Peel Ritchie in a joint paper maintain that a negative phase in the opsonic index produced by injection of tuberculin is evidence of the existence of tuberculosis and that the absence of such a fall in the index shows freedom from the infection.

The Dublin Journal of Medical Science.—In the May number of this magazine Dr. G. A. Gibson continues his review of the debt which we owe to Ireland with regard to the study of the circulation. Dr. J. Magee Finny records a case of maniacal chorea—one of the rarest of diseases, which is scarcely noticed in many text-books of medicine. The affection was apparently of rheumatic origin in this case but after death no organisms could be cultivated from the blood. The mental condition was maniacal in type, with delusions, hallucinations, and finally a semi-comatose state. In a short note on the detection of organic poisons in animal matter Mr. Marius Esposito revives a method proposed by Flandin in 1853—the substance being dried with quick-lime, powdered, and extracted with boiling absolute alcohol—which he believes is capable of giving good results.

The Medical Chronicle.—A Presidential Address on the Diagnosis of Early Pulmonary Tuberculosis delivered by Dr. S. Moritz before the Manchester Medical Society and published in the May issue of this magazine is notable for the review which it contains of some of the modern laboratory methods of diagnosis of this disease. Dr. Moritz speaks hopefully of the method of serum diagnosis introduced by Arloing and Courmont but is inclined to regard the injection of tuberculin as dangerous and places no faith in the opsonic index or its variation after the administration of tuberculin as a diagnostic sign. He concludes that repeated examinations may be needed to establish the presence or absence of tuberculosis. Dr. Gordon O. Lambert contributes an abstract of a thesis dealing with the effects of fever on the myocardium but the summary is so brief as to be rather unsatisfying.

The Birmingham Medical Review.—Of the problems which the x rays are called upon to solve, that of the presence of calculi is one of the most common. In an interesting article in the April number of this review Mr. J. Hall-Edwards discusses the present state of our knowledge in this field, and concludes that little help is obtainable in the diagnosis of gall-stones or of pancreatic calculi, while it is not often that prostatic concretions will be thus revealed. In the case of renal stones reasonable certainty can be obtained with skill and care. He discusses the methods adopted by different observers to obtain accuracy in this connexion. Dr. G. P. Mills traces a connexion between excretion of purin bodies and some irregular rheumatic conditions, and Dr. W. A. Potts discusses some cases of hæmorrhage met with in obstetric practice.

MEDICAL GOLFERS AT ASHFORD MANOR.—A team of medical golfers played the Bar Golfing Society at Ashford Manor on June 1st. The singles ended in a tie but the barristers won the foursomes and the match by five matches to four.

THE LANCET.

LONDON: SATURDAY, JUNE 15, 1907.

The Orations before the American Medical Association.

THE orations delivered at the fifty-eighth annual session of the American Medical Association held at Atlantic City from June 4th to 7th were such as to appeal to a very high tone alike of scientific and of professional thought, and to display a complete recognition both of the true foundations of medical activity and of the directions in which that activity may most usefully be exerted. In one important particular, at least, our transatlantic brethren have made advances which it is difficult for us to contemplate without some tincture of envy, for they have succeeded, almost completely in Pennsylvania and in varying degrees in other States and Territories of the Union, in placing public health under the effective protection of competent authority and in rescuing it from the clutches of the ignorance, official or non-official, which in this country is so constantly permitted to prohibit or to impede the due application of knowledge. Dr. SAMUEL G. DIXON, "Commissioner of Health of the Commonwealth of Pennsylvania," took as his subject, "Law the Foundation of State Medicine," and was able to describe "the most comprehensive and effective legislation for the protection of the public health ever enacted," and to say that, "armed with these strong and well-conceived laws," the administrators of the State had been able to accomplish certain definite results which had attracted the attention of sanitary reformers in all parts of the Union. The first and most important step in the indicated direction appears to have been the establishment of the office which Dr. DIXON holds, that of "Commissioner" or official head of a State board of health, with a seat in the Governor's cabinet, and with large executive powers. Among these a chief place must be accorded to a very complete system of control over the water-supply of the State, a system under which no new waterworks, no addition to works already existing, and no new system of sewerage or modification of an existing system, may be made without a permit from the Commissioner, a permit only to be granted after minute inquiry into existing conditions and into the nature and probable effects of the changes proposed. The prevention of the fouling of existing streams or gathering grounds is also among his duties, and the Board over which he presides has obtained State legislation for the immediate registration of births and deaths, for the notification of infectious diseases, for the gratuitous supply of antitoxin, and for the appointment of State health officers and county medical inspectors. A considerable freedom of local self-government has been preserved, but with the provision that if the Commissioner finds the sanitary administration of any municipality so faulty as to be a source of danger to the public he is authorised to step in and to assume complete control. Where our Local Government Board can only describe and recommend the Commissioner of Pennsylvania can take any action which the circumstances may require. The result is a "State system of sanitary administration, complete and symmetrical, its head at the seat of power in the State, untrammelled in the exercise of authority, reaching down through the subdivisions of county and township to the people, and in daily touch with every nook and corner of the State through its faithful allies, the physicians of the commonwealth." Dr. DIXON rightly admits that if this system should fail to accomplish great things for the health and happiness of the people the failure will be the result, not of the system, but of incompetence in its administrator.

If we compare the Pennsylvanian legislation as thus described by its official head with the state of things obtaining among ourselves, it is impossible not to be impressed by the complete difference not only in point of detail, but also, and even more remarkably, in principle. Pennsylvania regards sanitary administration as a department of government which is not only of the first necessity but which can only be conducted by the aid of knowledge; while the British Parliament has virtually decided that it is comparatively unimportant, that knowledge is unnecessary for its control, and that residence in the locality is the essential qualification. SMITH may be as ignorant as a horse of everything relating to the causation or prevention of disease, or he may have a direct pecuniary interest in the maintenance of some insanitary condition; but if JONES and ROBINSON, who are as ignorant and possibly as corrupt as himself, choose to select him as their representative on the local "authority," whatever it may be, there is no appeal from his ignorance or his ill-doing. Typhoid fever and diphtheria may prevail in his district, and the local schools may become institutions for the diffusion of epidemics; but SMITH, like MILTON'S Chaos,

> "Umpire sits,
> And by decision more embroils the fray."

The Local Government Board may send down inspectors to inspect and the inspectors may report and may recommend, but SMITH remains master of the situation and nothing can disturb him if only JONES and ROBINSON are true to their allegiance at the next municipal election. Dr. DIXON truly declares that "on State medicine depends the happiness of our people and the success of our nation. The industries on which we depend for our comforts, the wealth which enables us to enjoy them, and the arts which adorn and diversify our lives, are but the fruitage of the tree whose root is health." He draws a vivid picture of the applied sanitary science which enabled the Japanese to conduct on a gigantic scale and under the most adverse conditions a war in which the deaths and disabilities from disease were actually less than those from wounds, in which indeed the mortality from general causes scarcely exceeded that of the ordinary conditions of life; and he contrasts this with the fact that America, from mere impatience or neglect of laws with which she was well acquainted, "lost manyfold more of her brave troops on her own soil by preventable disease than by shot and shell at the seat of hostilities." Finally, he fully recognises that during conditions of ordinarily good public health the majority of mankind are neither wise enough voluntarily to submit themselves to the requirements of sanitary law nor righteous enough to be willing to exercise self-denial in order to save others from sickness, suffering, and death. He holds law and its enforcement to be necessary and urges that what is necessary for the State must, in order to be fully effectual, be extended to the Union. In no other way, he declares, can the health of a nation be preserved or the degeneracy of a people be prevented.

We have left ourselves but little space in which to notice the presidential address of Dr. JOSEPH D. BRYANT or the oration corresponding to the "Address in Medicine" at a meeting of the British Medical Association which was delivered by Dr. JAMES B. HERRICK of Chicago on the Relation of the Clinical Laboratory to the Practitioner of Medicine. Dr. HERRICK believes, what we think is to some extent true of this country as well as of others, that there is a tendency unduly to exalt the importance and the conclusiveness of the work of the clinical laboratory as compared with the results of careful observation at the bedside; and the essence of his learned and thoughtful address is an endeavour, without in any way minimising the former, to maintain the essential importance of the latter. The influence of the laboratory is but an extension of that which has been exerted for many years by the invention of continuously improving instruments of research, which, when they have not opened entirely new ground, have sometimes been conducive to undue neglect of older methods of examination and, what is of even more importance, to loss of the skill which those older methods had required and had tended to develop in those who followed them. There can be very little doubt, for example, that the facile application of the clinical thermometer has diminished the watchfulness of the average practitioner over variations of a less tangible and less easily ascertainable kind; or that the use of the sphygmometer, while increasing the knowledge of careful students of the character and variations of the pulse, might tend to diminish the *tactus eruditus* by which the physicians of an earlier generation strove against the difficulties of interpretation presented by what CELSUS called the *res fallacissima*. Precisely in proportion to the value of any method of laboratory diagnosis will be its liability to lead to erroneous conclusions in comparatively unskilled or careless hands; and Dr. HERRICK forcibly maintains that diagnosis should rest upon a due balance between clinical and laboratory observations, neither series being considered without reference to the other and each contributing its due quota to the conclusion. It is, after all, to the aggregation of phenomena—that is to say, to the sick man himself—that the attention of the practitioner should be primarily directed; and the proper function of the chemist, the bacteriologist, or the histologist is to determine the value of some portion only of the whole. The laboratory conclusions of to-day are not always confirmed by the labours of to-morrow; and it may, perhaps, be said of them, in their relation to medical practice, that, like literature, they are better calculated to furnish a walking stick than a crutch.

The presidential address of Dr. BRYANT was concerned, to quote Dr. BRYANT'S own words, with—

> (1) The organising of the medical profession of the country and its potential perplexities; (2) the elevating of the standard of medical education and its possible afflictions; and (3) the urgent demand for trustworthy medicinal means and of sincerer efforts on the part of every physician in securing a betterment of therapeutic methods.

The organising of the medical profession in a vast country like the United States of America is naturally a much more arduous task than in a small and compact country like our own and even among ourselves the unity of the profession is still far from being a fact. Dr. BRYANT is fully alive to the enormous benefits which a national Board of Health would confer, but he is not sanguine about the attainment of this ideal. He is by no means blind to the possibility of a highly organised body developing into a tyranny, but he looks forward to a time

> when, by the aid of Divine Providence, the medical profession of the United States shall have been made into "one compact organisation" and impelled in dutiful desires only by the highest motives of professional purpose and of public welfare, no enlightened opposition will oppose its desires, nor will irrational outcry, nor vagrant motives, find patient listeners or available foothold in the councils of the organisation or in those concerned in the requirements begetting of public confidence and respect.

And surely we, too, may pray for the coming of a similar time as regards our own land.

◆

The Simultaneous Occurrence of Intra-uterine and Extra-uterine Pregnancy.

THE occurrence of a multiple pregnancy in which one ovum is situated within the uterus and the other external to its cavity is a matter of much importance, not only because of the difficulties attending the diagnosis but also because of the dangers to the mother which accompany this abnormality. With a view to collating our knowledge upon this condition Dr. FR. VON NEUGEBAUER of Warsaw has collected a series of 169 cases from the literature and has added two observed by himself, or a sum total of 171 cases. The results he has embodied in a very valuable monograph[1] in which he sets out fully the conclusions at which he has arrived from his extensive study of the subject. More than half the total number of cases have been published during the last 12 years, no doubt because of their more frequent recognition by operation at the present day. An analysis of the histories given shows that four of the women had previously had twin or triplet pregnancy, while in four of the cases recorded there were three ova present. In three of these instances the twins were found in utero and in one case they were extra-uterine. Two of the patients had already undergone an abdominal section for an extra-uterine gestation. Dr. NEUGEBAUER points out that an examination of the site of the extra-uterine ovum reveals the fact that no less than nine of the cases, or 5·3 per cent., were examples of interstitial pregnancy, while in six the extra-uterine ovum was said to have been situated in the ovary.

The extreme difficulty of diagnosing this condition is shown by the fact that in only seven cases was a correct diagnosis made and confirmed by abdominal section; in eight cases the complication was, however, suspected, while in 21 it was found during delivery, or soon after delivery, that another extra-uterine fœtus was present. In 24 instances the correct solution of the case was only arrived at by a post-mortem examination. The conditions under which a correct diagnosis is most likely to be made are naturally those in which a patient the subject of an intra-uterine pregnancy is suddenly seized with the classical symptoms of the rupture of a tubal gestation. The further the normal pregnancy has progressed the easier will be the diagnosis; the most important point, however, is that the practitioner should bear in mind the possibility of such an occurrence and in all cases of doubt recommend an exploratory laparotomy so as to make certain of the exact state of affairs even at the risk of causing an abortion. In view of the heavy mortality of the children in these cases every care must be taken to safeguard the life of the mother, even at the risk of that of the children, except, of course, in such cases as, for example, one of inoperable carcinoma in which the mother obviously has only a short time to live. If it seems certain that the extra-uterine child is dead then operation may be postponed until after labour has occurred, so long as the ectopic fœtus does not offer any undue difficulty to the completion of delivery. With regard to the results as concerns the children, in 49 cases a living child was born from the uterus, while in no less than four cases a living extra-uterine fœtus was delivered by abdominal section and a child was born alive by the natural passages. Of 154 cases, 54, or 34·6 per cent. of the intra-uterine children, reached full term, and of these 49, or 31·3 per cent., were born alive; of the extra-uterine children, on the other hand, only 32, or 21·4 per cent., reached full term, and of these only 4, or 2·7 per cent., were delivered alive. A very remarkable fact is that in no less than 29 cases both children reached full term, while in one case of a triplet pregnancy, in which two of the children were intra-uterine and one was extra-uterine, this also occurred. Amongst 83 cases in which abdominal section was performed during pregnancy or soon after delivery 17 of the mothers died, or a death-rate of 19 per cent. The importance of treating these cases by abdominal section is seen by the fact that of 87 women operated upon in this way 70, or 80 per cent., recovered, while of 67 not treated by operation no less than 31 died. Unfortunately in most instances the cases have not been reported in sufficient detail to enable the important question to be determined as to whether the two ova were derived from one or from both ovaries. With regard to the etiology of this condition Dr. NEUGEBAUER is inclined to regard the intra-uterine gestation as a predisposing cause and no doubt there are some grounds for this view.

---

[1] Zur Lehre von der Zwillingsschwangerschaft mit heterotopem Sitz der Früchte, Fr. von Neugebauer. Leipzig: Klinkardt, 1907.

The most interesting problem connected with these multiple pregnancies is presented by the consideration whether they are examples of the fertilisation of two ova at the same time or of the occurrence of superfœtation. The different degrees of development of the two fœtuses is not of much value as proof one way or the other since it is not at all uncommon to find twin fœtuses differing very markedly in size and in weight. Further than this, it must be borne in mind that the likelihood of an extra-uterine fœtus being poorly developed in any case is very considerable. The case which is most suggestive of the occurrence of superfœtation in this series is one of those recorded by Dr. NEUGEBAUER himself. In this instance, after the death of the patient from internal bleeding, an eight to ten weeks' old fœtus was found in the uterine cavity and a fœtus of 17 days' growth which had apparently died at the time of the mother's death was found outside the uterus. Professor AHLFELD expressed the opinion when the specimen was demonstrated at Cassel in 1903 that it was an example of superfœtation. The frequency with which both fœtuses attain the full term of development possibly may be due, as suggested by Dr. NEUGEBAUER, to the fact that the normal pregnancy with its accompanying increase in the pelvic circulation favours the complete development of the extra-uterine fœtus. The ectopic pregnancy, however, with its numerous possibilities of complications, certainly endangers the life of the intra-uterine ovum. On the other hand, the death of one fœtus by no means certainly entails the death of the other, for CHROBAK extracted by abdominal section a living extra-uterine child five days after the birth of a full-term child, and WILSON did the same thing 26 days after the delivery of a living child from the uterus. It is impossible to over-estimate the danger of this form of multiple pregnancy, and, as Dr. NEUGEBAUER rightly concludes, the only correct line of treatment seems to be to consider the life of the mother alone and to rescue her from her peril by as early abdominal section as possible.

The Surgery of the Brain.

ON the due attention to details success often depends and of no work is this more true than of the work of the surgeon. Especially important is care in details in the surgery of the more vital organs of the body and in cerebral surgery pre-eminently is there the need of the closest attention to small points. Mr. CHARLES A. BALLANCE in his Lettsomian lectures before the Medical Society of London, which have recently been issued in volume form,[1] dealt with some important matters connected with the surgery of the cranial contents and he showed that one great cause of the excellent results of the present day is the advance in recent years of our knowledge of the structure of the brain and its membranes. Even the three lectures which Mr. BALLANCE devoted to the subject did not suffice for more than a brief consideration of many important points in cerebral surgery but on all the subjects on which he touched fresh light was thrown. The cases narrated were especially instructive. In one case, a patient under the care of Dr. JAMES TAYLOR, a man, 34 years of age, had symptoms suggestive of general paralysis and he narrowly escaped being sent to an asylum with that diagnosis. He had sustained an injury to the head, a considerable hæmorrhage had taken place into the arachnoid cavity, and the blood had become encysted and slowly increasing pressure was exerted on the brain. The "cyst," which was seven inches long, four and a half inches wide, and one and a half inches in thickness, was successfully removed and complete recovery ensued. A number of cases of traumatic encephaloceles have been recorded since Mr. R. J. GODLEE first described the condition in 1885 and Mr. BALLANCE relates a very instructive case occurring in a child four years old, an age greater than that at which the condition usually occurs. The child fell about 20 feet. Left hemiplegia was present with complete aphasia and some paresis of the left third nerve and a hernia cerebri developed. After operation the patient made a good recovery, the hernia cerebri soon disappearing, and two years later speech was almost perfect, except for some slurring during excitement; the weakness of the left leg was nearly gone, though the left hand was still paralysed.

---

[1] Some Points in the Surgery of the Brain and its Membranes, by Charles A. Ballance, M.V.O., M.S. Lond., F.R.C.S. Eng. 1907. London: Macmillan and Co. Price 16s. net.

Not many years have elapsed since lumbar puncture was first performed but now it has almost taken a place in the routine examination of certain cerebral and spinal cases in which the diagnosis is difficult, such as meningitis, when it is desirable to distinguish between the tuberculous and the non-tuberculous varieties. Lumbar puncture has also been used to a great extent for the purpose of producing what has been called "spinal anæsthesia," and the method has many advantages, though it has also several dangers and difficulties which were unsuspected by its introducers. Mr. BALLANCE has pointed out that lumbar puncture may also prove of value in traumatic lacerations of the substance of the brain when the patient is passing into the stage of cerebral irritation and he gives a very instructive instance. A man, 21 years of age, was thrown from a horse. The skull was not broken but he was unconscious for ten days. The right arm was paralysed and left ophthalmoplegia was present. The unconsciousness passed off but he became restless, irritable, and sleepless. By lumbar puncture from two and a half to three ounces of red-stained cerebro-spinal fluid were drawn off and on each occasion four hours of quiet sleep followed. Thus lumbar puncture may help both in diagnosis and treatment. When blood is poured out between the dura mater and the skull, as in injury to a meningeal artery or a venous sinus, the cerebro-spinal fluid obtained by lumbar puncture is clear and free from blood, but in cases of laceration of the brain substance or hæmorrhage between the dura mater and the brain, the fluid, as in the case related, is stained with blood. The lumbar puncture was also of distinct value in lessening intracranial pressure and so inducing sleep. Mr. BALLANCE is thus led to suggest that it may, perhaps, be advisable in some cases of ordinary apoplexy to relieve by lumbar puncture the pressure of the clot and serum on the nervous centres. We think the suggestion is happy and though it may prove to be of value in only a few cases it might assist in tiding over the time during which the brain is endeavouring to resume its functions. It is possible, too, that lumbar puncture might prove of service in temporarily diminishing intracranial pressure in case of cerebral tumour in which for any reason it is needful to postpone operation for a time. The operative treatment of internal hydrocephalus is also discussed and several cases are detailed in which this condition has been successfully treated, though it is hardly necessary to say that in these cases the mortality is great. Still, the fact that some of these cases recover after operative interference is very encouraging and should stimulate surgeons to persevere in attempting to improve the surgery of the meninges.

The second lecture on abscess of the brain was of great importance but it must yield in interest to the third which dealt with the surgery of tumours of the brain. It is hardly recognised by the general body of medical men how great has been the advance in recent years in this branch of surgery. Not many years have elapsed since the surgery of cerebral tumours began to exist and even now much of the progress that has been made seems to be unknown to a large proportion of the profession. Many of those who listened to that lecture must have been astonished at the enormous advance in this department of surgery. It cannot be denied that even now the mortality is heavy but in this connexion it must not be forgotten that every case, or nearly every case, is affected with a disease which, if left untreated, is certain to prove fatal. In many cases where recovery from the operation occurs the result is perfect and even when complete recovery does not ensue the improvement is often great or the progress of the disease is stayed. Moreover, statistics show clearly that the mortality is steadily decreasing. Our knowledge of cerebral technique is yearly improving; the surgeon can now with impunity undertake operations which would have been beyond his hopes at one time. We have undoubtedly still much to learn. All operative procedures on the brain disturb greatly its circulation and in hardly any other organ in the body is the maintenance of an equable circulation of so much importance. We are learning to know what can and what cannot be done and if the progress in the next ten years is at all on the same scale as that of the preceding decade we shall indeed see enormous progress. The future is full of hope but even the possibilities of the present are not adequately appreciated.

Annotations.

"Ne quid nimis."

THE NATURE OF INFECTIVITY IN RELATION TO TUMOUR GROWTH.

THE problem of the origin of cancer has always had a marvellous fascination for us all, and the theories that are advanced are almost as numerous as the facts on which those theories must be based. The latest contribution to the subject was contained in an address given by Dr. D. A. Welsh, professor of pathology in the University of Sydney, delivered at the First Australian Dental Congress in February last. An abstract of it appeared in our last issue. Mr. H. T. Butlin pointed out in the Bradshaw lecture at the Royal College of Surgeons of England that, whatever may be the ultimate etiology of cancer, as soon as a cancer cell is fully formed it behaves as a parasite. No longer is it obedient to the laws governing the organism in which it appears, no longer does it work for the good of its original owner, but it lives only for itself and, like a parasite, it flourishes at the expense of its host. Dr. Welsh in the address we have mentioned has carried the analogy a little further. He shows that in all tumours, both innocent and malignant, the analogy with infective processes is extremely great. In an infective process caused by bacteria we may in some cases find a merely localised infection which has no, or hardly any, tendency to spread beyond the point first infected. The infective process may, however, tend to spread locally; it infiltrates neighbouring tissues and has no well-defined limits. Other infective processes may be still more widespread. They do not limit themselves to the spot or neighbourhood where the germ first found entrance but by the channel of the lymph or blood stream reach distant parts of the body. To all these varieties tumours present very close analogues. The localised abscess caused by the local infection of a bacterium may be likened to the simple, benign tumour. It has a well-defined wall and it has no tendency to stray beyond the site of its first appearance, though it may increase in bulk. The local infiltration of a septic process bears a very close analogy to some tumours of a certain but slight degree of malignancy which spread locally, infiltrating the neighbouring tissues, but have no tendency to form secondary growths elsewhere. The virulent infective processes of pyæmia and septicæmia are very closely comparable with the very malignant growths which spread far from the original site, attacking distant structures by the medium of the blood and lymph streams. In these cases the "infective" agent is the living cell of the tumour, derived from the body in which it lives and not introduced from without. As to the cause of this suddenly acquired activity on the part of a cell of the body, Dr. Welsh has something more to say. He dismisses the idea of any lowly organism parasitically attacking and entering the cell and so causing it to assume the *rôle* of a cancer cell, and he tells us that the hypothesis has the demerit of being hard to reconcile with some of the known facts of tumour growth, though he does not tell us what these facts are. The theory which he advances is based mainly on the observations of Farmer, Moore, and Walker, that the nuclear divisions observed in some cancer cells are similar to those seen in the reproductive cells and not those which take place in ordinary somatic cells. It is further supported by the observation that some leucocytes have been seen to enter developing cancer cells. These are the foundations of Dr. Welsh's theory. He suggests that the fully developed cancer cell may be the product of the conjugation of a fixed tissue cell and a wandering leucocyte, both cells having undergone the nuclear metamorphoses of reproductive tissue. It has further been shown that developing cells may be induced to undergo increased and abnormal nuclear divisions when the chemical reaction of their environment is altered and especially when the alkalinity of the medium is increased, and there is some evidence that the body fluids of cancer patients commonly exhibit this increased alkalinity, and to this increased alkalinity he looks for the stimulus required. The theory is interesting and would go far to explain many of the phenomena of malignant disease but unfortunately some of its foundations are hardly as firm as could be wished. The work of Farmer, Moore, and Walker on the mitoses of cancer cells was doubtless of great interest but, as we pointed out at the time, its importance could easily be overrated, inasmuch as we were, and are, absolutely in the dark as to the real meaning of the special form of mitosis found in reproductive cells. Moreover, Victor Bonney has clearly shown that "gametoid" mitoses are not specially characteristic of the cells of malignant growths. They occur in perfectly innocent growths, such as the venereal wart. Further, Bashford and Murray have come to the conclusion that the appearances in cancer cells, which were believed to indicate the occurrence of a true "reducing division," i.e., a mode of division resembling that found in reproductive cells, are deceptive, and that the mitoses of cancer cells are really of the ordinary type found in somatic cells. Thus one of the foundation-stones of the theory proves to be incapable of yielding any support and without its aid we fear the theory must come to the ground. All that we know at present is that the forms of cell division in cancer cells are irregular; why or how we cannot explain. Such theories as that put forward by Dr. Welsh are of value in that they incite us to examine afresh the grounds for the opinions which we hold, to test thoroughly the bases on which our theories rest, and to revise from time to time the views which are generally accepted.

LIVINGSTONE COLLEGE.

SITUATED on the borders of Epping Forest at Leyton is a fine old country mansion now known as Livingstone College, which exists for the purpose of giving instruction in the elements of medicine and surgery to men who are already missionaries or who are preparing to become missionaries to isolated posts abroad. The need for some simple teaching that will enable missionaries to take care of their own health in places where medical aid is far distant was the keynote of several speeches made by missionaries at Livingstone College on June 5th, Commemoration Day, when the buildings were thrown open to public inspection. But it is not only the missionaries themselves who receive benefit from the teaching given at this college but also the natives of the country in which they may be working. Of course, it is only the more simple diseases which can be treated, for the course at the college is concluded in nine months, while those who enter for the course are required to sign a declaration that they will not take the title of "medical missionaries" or otherwise assume the position of a qualified medical man. It must be difficult for those who live in civilised countries and are able to call in medical attendance at a moment's notice to realise the position of those who are sick in a strange land far removed from medical aid, but if a man will travel 50 or 70 miles through forest and jungle to have a tooth drawn, as stated by two of the speakers, it is not difficult to imagine the position of one suffering from more serious complaints. In his report the Principal of the college, Dr. C. F. Harford, pointed out that there were on the committees of the college 12 medical men, six of whom had served abroad in connexion with six different missionary societies, so that they claimed to have some knowledge of the needs of the mission field. He claimed that Livingstone College should be supported on ethical, economical, and educational grounds. Ethical, because missionaries going to dangerous and isolated stations ought to be taught to care for their own health as well as to relieve the sufferings of the ignorant natives by whom they might be surrounded. Economical, because he believed that the college training would increase the usefulness of missionaries and save money spent in medical expenses and invaliding. Educational, because he considered that the scientific training was of immense importance to a missionary and prevented him from working in too narrow a groove, and he claimed that missionaries should be able to impart simple instruction in the laws of health to the people amongst whom they might be placed. He pointed out that a considerable proportion of the students at present at the college came from South Africa and from the continent of Europe, and though they were most heartily welcomed he earnestly appealed to the great denominational missionary societies to make more use of the college. There was a deficiency of over £500 in the college accounts and further help was urgently needed in order that the work might be carried on with true efficiency.

A SCHOLARSHIP IN DENTAL MECHANICS.

THE British Dental Association announces the foundation of the "Smith Turner scholarship in dental mechanics" of the annual value of £30. This scholarship is founded in honour of the memory of the late James Smith Turner and has for its object to help those students who, in the opinion of the fund committee, have financial difficulty in completing the dental curriculum. The scholarship is open to any registered dental student who has not completed the curriculum required for a dental qualification, will be awarded after examination, and will be tenable for one or two years at the discretion of the committee. We particularly approve of the very general terms of award. The scholarship money will be paid to any approved dental school in Great Britain and Ireland in discharge of fees, and the examination, which will be both practical and *vivâ voce*, will be held, so far as may be convenient, in rotation in the dental schools of the United Kingdom. The first examination will be held in London at the Royal Dental Hospital, Leicester-square, on April 8th, 1908. Applications must be received on or before March 1st, 1908, addressed to the Honorary Secretary, British Dental Association, 19, Hanover-square, London, W.

THE STREET NEWSVENDOR.

THERE is not much evidence in favour of the view, we are afraid, that personal cleanliness is a particularly jealous precaution taken by the man who sells newspapers in the streets. The calling is not a lucrative one and no doubt these men have a struggle to find sufficient nourishment and clothing for their bodies, in which circumstances it is not surprising that an occasional wash is viewed as a secondary consideration. Their *clientèle* is a very diversified one. The purchaser is now an errand boy, now a clerk, now a professional man, now a person of wealth or may be rank, so that should the newspaper seller's disregard for personal cleanliness amount to an infective process he may be scattering seeds of disease amongst all classes of society. It is somewhat astonishing to find how innocently regarded in general the newspaper is. There is no need to discuss the bacteriology of a newspaper which has come from dirty hands which have wiped soiled faces and which is tainted, it may be, also with the splashings and filth of the streets. The indictment is greatest against the evening papers, for it is chiefly these which are sold in the street. They are taken home to be read by others, they may circulate in the library, dining-room, and drawing-room, or may even be read in bed, notwithstanding the circumstance that the man who sold the paper may be, or is, obviously offensive in regard to his personal habits. This is no figment of the imagination, for we have seen men selling evening newspapers who bore unmistakeable evidence of their disgusting disregard for cleanly conduct. If street newspaper sellers are indispensable, and we do not dispute that they supply a public need, let them be clean in their business and show some attempt to keep and to sell their papers under conditions as cleanly and inoffensive as circumstances will permit. We know instances in which the street newsvendor appears as a perfectly clean respectable person from whom a newspaper may be taken without a shudder, and there should be no reason why such cases should be the exception rather than the rule.

ITALIAN PHYSICIANS ON "ALCOHOL."

"THE correspondence in THE LANCET on the Use of Alcoholic Beverages (writes an Italian contributor) is having its reverberation in the press of Italy, professional and lay. A distinguished consultant of the Piedmontese school is of opinion that neither the uncompromising assailants nor the out-and-out advocates of wine- or spirit-drinking represent the whole truth, which as usual, he thinks, lies between the two. Italians, indeed, scarcely admit, except in few cases, that immoderate consumption of alcohol exists among them. They use it as the better class of the English-speaking world use coffee or tea. Of course, even these beverages may be indulged in to excess; but that does not touch the question, namely, whether such a use of wine as prevails in Italy is not as innocuous, nay, on the whole as beneficial, as the use of tea or coffee prevalent in England. An Italian of the middle class will begin his day (as a rule earlier than in England) with a small cup of coffee and a rusk or bit of dry toast. On the strength of that he will do a good morning's work till about noon, when he will sit down to a *déjeuner à la fourchette*, with hot meat, accompanied with wine, and followed by fresh fruit. That keeps him going through the afternoon till the evening, when he dines, generally on fish and hot meat, and again with wine, followed by fruit, which latter he prefers uncooked, taking with it a little undiluted 'Chianti' or 'Lacrima Christi' on the principle, as he would say, of 'post crudum, nudum.' To accuse him on this regimen of the 'abuse of alcohol' seems to him absurd. He finds it compatible, as generations of his ancestors have found it before him, with the 'vita vitalis' of keen business enterprise or active professional life. He adjusts the quantity of wine which he takes to the benefit that he derives from it, practically admitting that if he exceeds that quantity he will suffer for it, as, according to Dr. King-Chambers in his treatise on 'The Indigestions,' afternoon teas and kettledrums and 'similar sloppy proceedings' used to be responsible for 'half the dyspepsia of the West End.' In his moderate use of Chianti or Lacrima Christi he maintains that he is no more taking 'alcohol' than the Englishman in his use of tea is taking 'theine.' Dr. Guido Fornaseri, in the leading Turinese journal, presses this argument home on the strength of clinical experience, winding up epigrammatically with the verdict of science as condemning 'alcohol' in excess; with 'attenuating circumstances' when it is freely diluted; and with the *benefizio del perdono* (the concession of pardon) when, so diluted, it is taken in moderation."

INFANT MORTALITY AND ITS PREVENTION.

IN an excellent paper read before the sessional meeting of the Royal Sanitary Institute on May 31st Major R. J. Blackham, D.P.H., R.A.M.C., dealt with the problems attending infant mortality both under the conditions of civil and army life. He classed the necessary preventive measures under three heads, those directed towards the mother, those directed towards the child, and those requiring special statutory powers. As regards the mother, he insisted on the extreme importance of educating elder girls in the care of infants and young children to fit them for their future responsibility and quoted a very apposite passage from Herbert Spencer, in which that philosopher maintained that the education of the children of his day was limited to a "curriculum for celibates," a reproach from which we are not yet free. Major Blackham suggested that instruction on these matters should be given under the supervision of medical men and specially trained nurses and that the Royal Sanitary Institute might issue a certificate in infant hygiene to qualify nurses for such appointments. He next pointed out the necessity of the proper care of poor women during and after the puerperium and he showed by a table that the prospect of passing through the first year of life is twice as good for the soldier's infant as for the child of the neighbouring civilian, which was largely attributable to the increased care taken of military mothers; he recommended to civil attention the system adopted by the French Society of Nursing Mothers; the last necessary provision for the mother was "the further supervision of female labour in factories and the prevention of women from engaging in arduous labour during the three months immediately preceding and following parturition." In this respect he recommended the institution of factory crèches as being not only good for the mother and the child but also affording valuable training schools for older girls in infant management. Turning to the measures directly affecting the child he dealt with them under three further heads—the provision of a pure milk for artificial feeding, including the inspection and control of milk from the source to the consumer, the appointment of lady health visitors, and provision for the earlier registration of births. With regard to the first of these he pointed out the excellent example set by France and with regard to the last the lesson taught by the ex-Mayor of Huddersfield's philanthropic experiment. Major Blackham then grouped the new legislation required into three Bills embodying the following measures:—

1. A short Act on the lines of the Roussel law of France, prohibiting (*a*) the use of undigested farinaceous foods for infants less than seven months old; (*b*) the sale of infants' foods which do not bear an analysis on each packet and a certificate from a Government analyst that they are non-injurious; (*c*) the use of feeding bottles with tubes and dummies or infant soothers.

2. An Act amending and consolidating the Infant Life Protection Act of 1897 and the Prevention of Cruelty to Children Act of 1904. This Act would: (*a*) provide for the further protection of children sent out to nurse; every child adopted for lump sum or received for reward, whether alone or with others, would be inspected by Government inspector till it attained the age of seven years; (*b*) prohibit and penalise the leaving of young children alone in circumstances of danger; (*c*) authorize the distribution by registrars of circulars giving advice on the care of children; (*d*) control and vigorously restrict the life insurance of the infants.

3. An Act replacing the present Dairies, Cowsheds, and Milkshops Order of the Local Government Board.

In concluding this valuable paper the writer pointed out the important fact that "the question of infant mortality seems to be one which draws the practitioners of curative and preventive medicine closer together than any other subject." The tables comparing civilian and army infant mortality were striking in showing the increased chance of life of children reared under service conditions.

MEAT, MILK, AND DISEASE.

WE have before us three documents—namely, the report of the medical officer of health of the City of London, Dr. W. Collingridge, for the five weeks ending May 18th; a special report, dated June 1st, to the health committee of the Portsmouth town council by its medical officer of health, Dr. A. Mearns Fraser; and, lastly, a report of a case heard on June 4th at the Mansion House police-court. All these documents deal with diseased meat or milk which is deliberately offered to the public for sale as food for themselves and their children. Dr. Collingridge draws special attention to the very ineffective way in which the laws for the inspection of food products in the United States of America are carried out and he gives two instances. In the one case a forequarter of chilled American beef bearing the inspection label of the United States Department of Agriculture was sent by a firm in Smithfield Market to a customer at Reading. A local inspector there examined the beef and found that although no tuberculous lesions were evident externally, yet the sternal glands into which he cut were diseased. The meat was destroyed with the consent of the owner. Again, on May 5th a quantity of plucks from a box bearing the inspection label of the United States Department of Agriculture were seized as unfit for food. The label was stamped, "Est. no.1 Cancelled." As doubts existed as to what this meant the matter was submitted to the United States Bureau of Animal Industry, which replied explaining the lettering and adding, "There is nothing to indicate that the contents of the box bearing this label was condemned by the United States inspectors." So much for America: now let us look at home. Dr. Fraser calls the attention of his authority to "the menace to health through the systematic trade in diseased animals, principally tubercular cows, that is carried on in country markets near Portsmouth." Dr. Fraser gives a list of animals sold nearly all in Petersfield and Chichester, with their probable destination, which in most cases was London. The list covers the period May 30th, 1906, to May 29th, 1907, and includes 72 cows. The price of these animals varied from 5*s.* to 80*s.*, and many of these, according to Inspector Monckton, the borough inspector, who attended the markets, where, of course, he had no legal *locus standi*, showed "unmistakeably that they were badly affected with tuberculosis." Dr. Fraser's opinion is that the only way of stamping out this trade is the systematic inspection of live-stock. Turn we now from the simple rustic to the town trader. On June 4th, at the Mansion House police-court, Messrs. Field and Co., Limited, fruit merchants, of 10, Monument-street, were summoned before Alderman Sir W. Vaughan Morgan by the Stepney borough council for selling 1290 tins of condensed milk which were unfit for human food. Thomas Palmer, their manager, was summoned for aiding in the offence. A witness named Wear, who had purchased the 1290 tins, and who admitted that he had been proceeded against and fined £30 10*s.*, including costs, for having the stuff in his possession, said that after this prosecution he saw Palmer who advised him not to trouble, "as the matter would blow over and the loss would be made up on another deal"; also "that if he would plead guilty and keep the company's name out of the case they would pay his fine and would recompense him." Mr. Leycester, counsel for the defence, denied the truth of these conversations but admitted that all the tins were bad. He said that the milk had been sold as pig's food, although Wear stated in evidence that he had bought it for human food. In the end the company was fined £25 and £5 5*s.* costs and Palmer a like sum. The trade in diseased meat and putrid milk, to say nothing of adulterated food-stuffs, will never be put an end to until the vendors are treated as the poisoners which they really are.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN a summary of several investigations, chiefly statistical, which he has made on the subject of epidemic cerebro-spinal fever, Dr. A. K. Chalmers, the medical officer of health of Glasgow, states that there is no reason to suppose that food conveys the infection. In fatal cases patches of congestion were found in the intestine, sometimes in the duodenum, but more commonly towards the lower end of the ileum. Temporary diarrhœa sometimes preceded an attack, but efforts to discover the meningococcus in the intestinal discharges or in the bowel wall have not hitherto been successful. Some of the cases suggested that the period of incubation might be less than a day, but, on the other hand, some secondary cases occurred in the second week, and others in the second month after known exposure. Although nasal discharges were from time to time examined the organism was recovered only three times from patients by swabs taken through the anterior nares. It was recovered, however, from the naso-pharynx of four "contacts." Dr. Chalmers remarks that "carrier" cases and spray infection would completely explain the method of spread were the organism recoverable in a larger proportion of "contacts." Among the patients observed in Glasgow mixed infections were rare. In two such cases the meningococcus was associated with the tubercle bacillus in one and with a diplococcus in the other. In 106 examinations, "71 of which were by lumbar puncture after death and 35 were necropsies," the meningococcus was found alone in 71 cases, the pneumococcus alone in two cases, the meningococcus and the pneumococcus together in one case, the tubercle bacillus in four cases, and a *streptococcus* in one case, whilst in 27 the results were entirely negative. With regard to school association, it has to be remarked that the onset of the disease is very sudden and usually prevents school attendance from the beginning. In 38 schools single cases only occurred, in 17 schools there were two cases each, in six schools there were three cases each, and in four schools there were four cases each. In Scotland during the week ended June 8th there were 15 deaths from this cause registered in Glasgow, five in Edinburgh, three in Leith, and one in Paisley. In Glasgow the weekly report issued on June 7th showed that there were at that time 104 cases under treatment. In Belfast during the week ended June 8th ten deaths from this cause were registered.

THE CHILD'S HOLIDAY.

THE health of the little ones who live in the poorer and generally unhealthier areas of our great cities is a matter of the first importance to us all. Not only humanity but self-interest, our interest in our population, insures this. To give these children when living in London a fortnight's holiday in the country does not at once fit them to become either useful workers and desirable members of the community or healthy parents of a new generation, but it affords an admirable stimulus to all manifestations of their physical and moral progress, and therefore the Children's Country Holiday Fund deserves the best support which we can give. Entirely unsectarian in its character, the society year by year extends its good work and is only limited in its operations by the amount of the subscriptions which it receives from the public. From the annual report which has just been issued we learn that during the year 1906 43,442 children were sent to country cottages in the south of England, and the executive of the society expect that during the forthcoming season there will be an even greater demand upon the fund for assistance. When it is remembered that there are more than 800,000 children on the rolls of the London (including West Ham) schools 43,000 appears as but a small proportion to whom to extend the advantages of a visit to the country, particularly when we remember that quite possibly one-half of the elementary school population of London never leave the metropolis for a single night throughout the year unless they happen to be among those selected for a country holiday. The report of the fund, which can be obtained from the secretary, should be read by all who take an interest in what someone has described as "God's problem awaiting man's solution—the little child." Contributions should be sent to the secretary or the treasurer at the central offices of the fund, 18, Buckingham-street, Strand, London, W.C.

RAYNAUD'S DISEASE.

IN the *Western Canada Medical Journal* for April of this year Dr. G. A. Gibson of Edinburgh publishes some interesting observations on Raynaud's disease. He deals only with those cases in which the origin of the symptoms is obviously reflex in character and describes two instances in which the ordinary clinical symptoms of the malady were well marked. They were both men, one being 18 and the other 23 years of age. Ordinary treatment proved of no avail, and as Dr. Gibson considered that the condition might be produced by renal mobility, in each case the operation for fixation of the kidney was performed. In the first case the effect of the operation was remarkable. The patient was kept on his back for a month after its performance, and when he was allowed to get up it was found that all the symptoms of Raynaud's disease had disappeared. Although the weather was still cold, the discolouration of the affected parts of the body had disappeared, and the contraction of the veins never recurred. The result in the second case was equally satisfactory. Dr. Gibson records these cases as excellent illustrations of a variety of Raynaud's disease having its origin in reflex disturbances and falling into the same category as the angina pectoris vaso-motoria of Landois and Nothnagel. It might, of course, be suggested that mobility of the kidney is in itself scarcely sufficient to produce such widespread disturbances as are found in connexion with Raynaud's disease. Dr. Gibson points out, however, that moveable kidney is a fertile source of palpitation and of tachycardia and he believes that there can be no doubt of its power to bring about all the vaso-motor changes which are summed up under the title of Raynaud's disease.

"GREATEST OF THESE."

WE have received a letter from Mr. Sigismund Goetze giving his reasons for thinking that our recent allusion to his picture, which bears the above title and which is now on exhibition at Burlington House, was unfair. Mr. Sigismund Goetze's letter was marked "Private" or we should have been happy to publish it. The words to which exception is taken were as follows: "The central figure is a lady suckling a child of four, which is somewhat of a physiological exploit"; and the question is how old the infant which he has painted appears to be. We have scrutinised the picture closely since Mr. Goetze's letter of protest and we have come to the conclusion that the truth lies somewhere between Mr. Goetze's intention and our critic's estimate. The infant does not look four years old and we regret that needless exaggeration should have been employed in such a way as to give pain to the artist. But we find the infant too big, too muscular, and too old-looking as displayed in Mr. Goetze's picture for the occupation in which he is depicted.

ST. PANCRAS MOTHERS' AND INFANTS' SOCIETY.

AS a result of the efforts of Dr. J. F. J. Sykes, the medical officer of health of the borough of St. Pancras, a good deal has been done in that neighbourhood to encourage the natural feeding of their infants by poor mothers and to discourage as far as possible artificial feeding. In this endeavour he has been assisted by a band of lady health visitors and it would appear by the infant mortality rate in St. Pancras last year that some measure of success has been attained. A further step in the same direction is now contemplated by the establishment of the above society. It has for its object the provision of a school for nursing mothers to which they will be invited to go to learn how a baby should be clothed, fed, washed, and tended. It is proposed to have a trained teacher on duty at certain times to give practical instruction on the babies themselves. The mothers are to be taught how to feed their babies and how to cut out and make baby clothes, and if it is found that they take kindly to such teaching it is hoped that cooking, nursing, hygiene, and needlework classes may also be organised. A special feature is an attempt to attract newly married girls to go to the Mothers' and Babies' Welcome, as the institution is appropriately to be named. A further suggestion is that in order to assist the poor mothers properly to nurse their babies cheap dinners, which will be utilised as object lessons in the economical preparation of nourishing food, shall be provided at a small cost. A department is also to be formed in which non-nursing mothers, on the production of a certificate from a medical practitioner, a dispensary, or a hospital, will be taught how to procure pure milk and the best methods of hand-feeding. It is also intended to establish a provident club for parents to encourage the forming of some provision during the time when the mother is laid up, a consulting-room where mothers and babies may be examined and advised, and a bureau for fathers where their circumstances may be investigated and advice given, we presume as to the obtaining of work. As it is obvious that a scheme of this kind cannot be initiated without a good deal of expense an appeal is being made to the inhabitants of the neighbourhood to subscribe towards the expenses of the Mothers' and Babies' Welcome. The scheme is one of considerable interest and should prove, if properly and efficiently carried out, a great boon to the poor mothers of St. Pancras. It is founded partly on the scheme which has been started in Chelsea for providing dinners for nursing mothers and partly on the school for mothers which is in existence at Ghent. We trust sincerely that the Welcome may meet with the support which it deserves.

MEDICAL EDUCATION IN LONDON: THE "CONCENTRATION" QUESTION.

IT is evident that the present position of the movement for the concentration of earlier medical studies under the University of London is receiving much consideration. A letter from Mr. Cosmo Bonsor, the treasurer of Guy's Hospital, containing a resolution on this subject recently passed by the teachers in the medical school of that hospital is published in our columns to-day. In forwarding this resolution to the Principal of the University Mr. Bonsor states that it must not be construed as adverse to the principle of concentration but only to the particular proposals at present sanctioned by the University. As these particular proposals are the outcome of the most careful consideration of the question extending over many years and have been before the public a considerable time, this negative attitude towards them is not very helpful. A meeting of the Faculty of Medicine of the University of London has been called to consider the present position of this question for Friday, June 28th. Perhaps some useful suggestions as to possible modifications of the present scheme may result from the deliberations of the Faculty. It seems clear that some compromise between the conflicting interests of teachers of different parts of the curriculum and of competing institutions must be arranged before any useful report to the Senate can be agreed upon. If this is impossible it would appear necessary for the Senate to set up a sort of informal commission to take evidence upon the subject and to prepare a report for the guidance of the Senate upon this urgent and difficult question.

THE PROBABLE ORIGIN OF SYPHILIS IN EUROPE.[1]

IN this little pamphlet Dr. L. Bousfield has gathered together passages from authors both ancient and modern which show arguments both for and against the existence of syphilis in Europe prior to 1494. The question as to whether this disease did or did not exist in Europe prior to 1494 may be set down in the same category with the two problems mentioned by Sir Thomas Browne as unsolved though not insoluble. Dr. Bousfield asks that allowance may be made for him in having omitted certain evidence. He quotes from various ancient medical authors such as Aretæus and Galen passages which certainly might be descriptive of syphilis and we should say probably are so. He has, however, omitted one from a layman, namely Persius, which is quite worth quoting. It occurs in his Third Satire:

> "Tentemus fauces, tenero latet ulcus in ore
> Putre ......"

The satire, it must be remembered, deals with the fast young men of Rome. Dr. Bousfield gives the well-known passage in Martial, Epigramm. VII., 71, commencing "Ficosa est uxor." The epigram is all about figs, and, as Dr. Bousfield says, there is a play on the words and the exact meaning is very doubtful. What exactly Martial had in his mind it is impossible to say, but we think there is little doubt that there is an allusion to matters such as second-hand book-sellers call "curious." Whatever "ficus" meant in Latin it is certain that the Greek word for a fig—i.e., σῦκον—also meant the *pudenda muliebria*. Moreover, "fig," "fico," and "figue" are all found in the respective languages as expressive of the same organs. Therefore the epigram may very well refer to a venereal sore. Dr. Bousfield gives full value to the views of those who think that the disease called leprosy by mediæval writers was in many cases syphilis. His final conclusions are that syphilis "was either a new disease (in Europe) or a disease which appeared new to the living generation" in or about 1494. The pamphlet is interesting as an introduction to the study of a subject of vast interest and one in which there is still room for arduous research.

THE EARLY NOTIFICATION OF BIRTHS.

THE Notification of Births Bill came before the Grand Committee of the House of Commons during last week and the Bill was then altered in many details. A most important modification was that making it an adoptive Act instead of a compulsory one, that is to say, it is only to apply in the area of any local authority which chooses to adopt it. As the Bill at present stands it provides for the notification of a birth by the father and by any person in attendance on at the time of, or within six hours after, the birth, in writing to the medical officer of health of the district. This must be done within 36 hours of the birth and applies to still-born children as well as to children born alive. Unfortunately, no definition of a still-born child is given in the Bill and no doubt this will lead to confusion and evasion of its provisions. Probably if the Bill passes it will undergo still further modification after consideration by the whole House. The Bill was down for this purpose on Monday, June 10th. It was not, however, reached and the matter was deferred until Thursday, the 13th. It is difficult to understand whether the notice of births is to be the duty of the nurse or of the medical man, since both may be said to be in attendance at the time of birth. But probably it is intended to be done by the medical man. This will throw a considerable amount of extra work on the shoulders of the already hard-worked practitioner, but the more certain and earlier notification of births thus obtained will tend very markedly, at any rate in those districts in which full advantage is taken of the knowledge by the local medical authorities, to the saving of infant life. That such a duty should be laid upon the medical man without any payment being made for it is we think unfair, but any attempts to insist upon the payment of a fee for such certificates is likely to wreck any chance that the Bill may have of passing. It is a matter for regret that no definition of a stillbirth has been inserted in the Bill, as, after all, it is chiefly the compulsory notification of such births which is of the greatest importance. As far as it goes this short Bill might prove of great service, but it is, we think, unfortunate that it has not been made compulsory on all local authorities to adopt it.

AN extra afternoon meeting of the Royal Medical and Chirurgical Society will be held at 20, Hanover-square, London, W., on Wednesday, June 19th, at 5.30 P.M., to listen to a paper by Mr. D'Arcy Power, F.R.C.S., F.S.A., the reception of which by the society constitutes an interesting departure in the practice of that body. Mr. Power's paper is upon Dr. Walter Bayley and his Works, 1529–1592, and as he has ere now proved himself to be a true antiquary, every suggestion that may throw light upon the life or work of Bayley will be received with interest. We hear that in the course of his researches he has discovered Bayley's will, of which extremely interesting document he will give a transcript. To add to the usefulness of the meeting Fellows and others are contributing various objects of antiquarian interest, which will be displayed. Mr. Power, for example, will exhibit a letter of Archbishop Strafford, Abbot of Westminster, dated April 19th, 1445, addressed to all barber surgeons in the City of London, directing them to cease from opening their shops on Sunday on pain of excommunication.

---

[1] The Probable Origin of Syphilis in Europe, by L. Bousfield, M.A., M.D. Cantab. London: S. F. Hodsoll. Price 2s. Pp. 23.

THE secretaries of the National Committee of the Fourteenth International Congress of Hygiene and Demography request those who propose to attend the Congress to send in their names to them, stating the titles of their papers, if any, and whether they will attend the Congress as delegates or ordinary members. For information regarding the Congress, which will be held in Berlin from Sept. 23rd to 29th next, application should be made to Professor G. H. F. Nuttall, F.R.S. (honorary secretary), 3, Cranmer-road, Cambridge.

ON June 11th the Queen, with the Queen of Denmark and Princess Victoria, paid a private visit to the exhibition of Red Cross appliances, which closes to-day (Saturday), at Earl's Court. We hope to publish an account of the exhibits in a forthcoming issue of THE LANCET.

TELEGRAMS from the Acting Governor of Hong-Kong, received at the Colonial Office, state that for the week ending June 1st there were 10 cases of plague and nine deaths from the disease, and for the week ending June 8th 15 cases and 12 deaths.

Dr. W. J. R. Simpson will deliver the Croonian Lectures of the Royal College of Physicians of London on Tuesdays and Thursdays, June 18th, 20th, 25th, and 27th, at 5 P.M., at the College, the subject selected being "Plague."

As we go to press we learn that the amount at present received by the Metropolitan Hospital Sunday Fund is £16,000. As usual, we shall give lists of the amounts of the principal collections and donations in future issues.

THE name of Mr. Henry Morris should have been included among those appointed to serve on the Dental Committee of the General Medical Council.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE present constitution of the Council is as follows. There are 24 members and three retire each year, but if the time of retirement of a member of the Council should arrive when he is President he does not retire but he becomes entitled to remain a member of the Council for another year. In the natural course of events Sir John Tweedy would have retired in 1904, but he was twice re-elected President, so that his term does not come to an end till this year. The list given below shows the dates of retirement of the present members. The date of the first election is given in every case in which the member has been elected to the Council more than once.

Retire in 1914: Mr. G. A. Wright, Manchester Royal Infirmary; Mr. Henry Morris, Middlesex Hospital (first elected, 1893); and Mr. F. Richardson Cross, Bristol Royal Infirmary (first elected, 1898).

Retire in 1913: Mr. Edmund Owen, St. Mary's Hospital; Mr. Rickman J. Godlee, University College Hospital; and Mr. C. H. Golding-Bird, Guy's Hospital.

Retire in 1912: Mr. H. Gilbert Barling, Birmingham General Hospital; and Mr. Anthony A. Bowlby, St. Bartholomew's Hospital.

Retire in 1911: Mr. H. T. Butlin, St. Bartholomew's Hospital (first elected, 1895); Mr. G. H. Makins, St. Thomas's Hospital; and Mr. C. T. Dent, St. George's Hospital.

Retire in 1910: Professor Howard Marsh, St. Bartholomew's Hospital and Cambridge (first elected 1892); Mr. J. H. Morgan, Charing Cross Hospital; and Mr. H. H. Clutton, St. Thomas's Hospital.

Retire in 1909: Mr. A. W. Mayo Robson, Leeds Infirmary (first elected, 1893); Mr. W. Watson Cheyne, King's College Hospital; and Mr. R. Clement Lucas, Guy's Hospital.

Retire in 1908: Mr. J. Ward Cousins, Royal Portsmouth Hospital (first elected, 1895); Mr. A. Pearce Gould, Middlesex Hospital; and Mr. W. Harrison Cripps, St. Bartholomew's Hospital.

Retire in 1907: Sir John Tweedy, University College Hospital (first elected, 1892); Mr. H. W. Page, St. Mary's Hospital; Mr. C. W. Mansell Moullin, London Hospital; and Mr. Frederic S. Eve, London Hospital.

It will be seen that of the 24 present members of the Council 19 are representatives of London hospitals and five are connected with provincial hospitals. Of the 19 London members four come from St. Bartholomew's; two members each come from Guy's, the London, Middlesex, St. Mary's, St. Thomas's, and University College Hospitals; and one member each is provided by Charing Cross, King's College, and St. George's Hospitals.

There are this year four vacancies and for these there are seven candidates. Sir John Tweedy has decided not to reapply, but the three other retiring members—namely, Mr. Page, Mr. Mansell Moullin, and Mr. Eve—will offer themselves again for election. There are four new candidates—Mr. Charles Higgens of Guy's Hospital, Mr. W. Bruce Clarke of St. Bartholomew's Hospital, Mr. Charters J Symonds of Guy's Hospital, and Mr. W. D. Spanton of Hanley. Of these Mr. Bruce Clarke and Mr. Symonds have been candidates previously. The day of election is Thursday, July 4th.

MEDICINE AND THE LAW.

The Control of Medical Certificates.

FROM time to time difficulties arise between the parents of children of school age and the local education authority as the result of the production by the former of a medical certificate which states that the child is either fit or unfit to attend school. It is a professional axiom that a medical practitioner expects his *bonâ fide* certificate of health to be accepted without question, but occasionally the validity of such documents is contested. Two recent cases may be given in illustration. At a petty session for hearing school-attendance summonses at St. George-in-the-East a mother endeavoured to excuse her daughter's absence from school by producing a medical certificate which stated that the child was in such a condition as to be unfit to attend school, her complaint being pediculosis capitis. The justices declined to accept this certificate as a sufficient excuse, it being a matter of common knowledge that the repeated neglect of a parent is solely responsible for this verminous state; indeed, they fined the mother somewhat more heavily than in ordinary cases of summons for non-attendance at school. A few months back the public health (education) department of the London County Council issued a notice to the effect that it was considering whether a child who had been excluded from a public elementary school on account of diphtheria or other sore-throat should be readmitted to the school unless previously a medical certificate had been delivered which stated that the throat of the child was bacteriologically free from the diphtheria bacillus; the necessary clinical research would be executed free of cost to the parent; a medical certificate based on other signs would not be accepted. This innovation was the result of the expression of opinion made by the Incorporated Society of Medical Officers of Health. The proposal has been objected to as an apparent dictation to medical practitioners as to their methods of arriving at a diagnosis; the London County Council was requested to reconsider the novel legal position which would be established. It has now been advised that the code of regulations for elementary education provides that no child shall be refused admission to a public elementary school on other than reasonable grounds to be determined in case of dispute by the Board of Education and, therefore, as there is little doubt that the Board of Education would decide that it is reasonable to require such bacteriological examination provided the parents were enabled to obtain such examination without expense, the London County Council is acting within its power in demanding that form of medical certificate.

Hearsay Medical Evidence.

The statements made by an injured person to his medical adviser are sometimes included in the exception to the rule of the law of evidence which prohibits "hearsay testimony" from being adduced in court. Such statements recently formed the subject of dispute in the case of Gregory v. the State, tried in the Appellate Division of the Supreme Court of Alabama. The proceedings arose upon a charge of homicide. The alleged statement of the deceased patient that he had "no feeling in the feet or legs and had burning in the stomach" was testified to by a medical witness; the admission of such hearsay testimony was challenged. The decision was that, had the words quoted referred to the cause or way in which the accident resulting in the injury had occurred, they would have been excluded, for otherwise that would have been admitting a narrative of past events which should have been proved in the usual way. Here, however, what was desired to be put in evidence was the character, locality, and symptoms of pain which aided in explaining the bodily condition of the injured man and so assisted the medical adviser in forming an opinion of the nature and extent of the injury. In narrating what the patient said he felt and suffered the physician was stating some of the facts which enabled him to arrive at a correct diagnosis of the injury and to prosecute a line of treatment; as his diagnosis and his treatment may be questioned in court the clinical facts which led up to his conclusions should also be allowed. It is obvious that this form of hearsay testimony can only be allowed where the patient is already deceased, otherwise he should be produced as a witness in court. In attending what appears to be a case of attempted homicide it is well to note down all comments made by the victim; they may be useful later.

The Case of Mr. Burnyeat.

Mr. W. D. Burnyeat, M.P., has no doubt learnt a lesson during the past fortnight which he will not forget, and it is to be hoped that his experiences will have a more extended usefulness by enabling some of those foolish persons who dose themselves with drugs the qualities of which they do not understand to appreciate the kind of consequence which may follow such conduct. It is not necessary to recount in detail that which the daily newspapers have already related in their reports of the hearing of the charge against the member for Whitehaven at the police-court. Having arrived early in the morning at a hotel in London after a night journey and being seized with griping pains after breakfast he took "chlorodyne," pouring it on his tongue undiluted. His own evidence was that he was not in the habit of using "chlorodyne" but that he had done so on six or eight occasions during his life and that he usually carried some with him when travelling. At all events, he had in his bedroom on the morning in question a bottle of chlorodyne of which four-fifths of the contents had been consumed as well as an unopened bottle and he repeated at intervals during the day the process of swallowing chlorodyne "neat" until at some time after 6.15 P.M. he had emptied both bottles. Meanwhile he had taken no food, as he was still feeling very unwell, but had done some work at his own chambers in the Temple, and had attended a consultation at the chambers of a King's Counsel in Lincoln's-inn a little after 4 P.M. Walking westwards along the Strand after finishing the chlorodyne, as mentioned above, he felt faint and went into the Gaiety Restaurant and had two small "whiskies and sodas." After this, according to his own evidence, he remembered entering an omnibus with a view to reaching Charing Cross and recollected nothing further until he found himself in a cell at Kennington-road police station, whither he had been taken on an ambulance by a constable who had found him apparently drunk and incapable outside Waterloo Station. As to the formalities which preceded his release from the police station he had no recollection when late on the following day he saw his name placarded on the bills of the evening newspapers as having failed to surrender at the police-court. The charge of drunkenness against him has now been heard and dismissed, there being abundant witnesses of unimpeachable integrity as to his temperate habits and good character generally, and as to his sobriety on the day in question, followed by the evidence of Dr. A. P. Luff, Mr. A. J. Pepper, and Dr. J. S. Bury of Manchester, to the effect that the amount of chlorodyne which he had imbibed during the day and which had accumulated in an empty stomach until finally diluted and absorbed through the action of the whisky and soda-water would be calculated to produce exactly the symptoms which the police had observed and which Mr. Burnyeat, so far as he was able, described. Accordingly, Mr. Burnyeat was acquitted of the charge brought against him by the police, as he was clearly entitled to be, but surely he must remain convicted before the tribunal of his own conscience of being a very unwise person, in spite of his legal attainments and of the mental qualities which have won for him at an early age a seat in the House of Commons. That an educated man should dose himself with "patent" nostrums instead of having recourse to a medical practitioner when feeling as ill as he no doubt did would hardly be credible if examples of such imprudence did not occur frequently; it is less easy to understand how a man whose intelligence and education may be assumed to have been above the average should persist in taking for a whole day a compound the general characteristics of which are so well known as those of "chlorodyne." His own sensations must at least have shown him that he was doing himself no good, and he must presumably have drawn the less reasonable conclusion at the same time that he could consume a bottle full of it without its having any effect of any kind. We have congratulated him upon having vindicated his character for temperance; we must also express the hope that he realises his good fortune in having survived to do so. Apart from the amount of the drug which he consumed he must have escaped considerable danger during the interval between his visit to the restaurant and the time when the police took charge of him.

NOTES UPON HEALTH RESORTS.

(FROM A SPECIAL CORRESPONDENT.)

THE AUSTRIAN SPAS.

IN various parts of the Austrian Empire there are places known as "kurorte," a word which may be translated health resorts or spas, but which conveys the additional meaning that the places in question are officially recognised as such, and the Government permits the use of this appellation only when the local conditions deserve it on account of the salubrity of the air or the therapeutic value of the mineral springs. The title "kurort" means also that the visitor has to pay a certain sum (*kurtaxe*) for the privilege of using the thermal springs as a contribution to the cost of keeping the place up to date. The sum to be paid varies according to the place and the length of the stay that is made. As a rule, the first eight days are free from this tax and the total hardly ever exceeds £2. The accommodation is mostly on the continental system. The English custom of boarding-houses is only exceptional and is prevalent in such places as are more frequented by English and American visitors in the Tyrol, whilst the majority of places has for the visitors the system of furnished rooms and flats or hotel accommodation. With the exception of one or two of the most fashionable kurorte, like Carlsbad or Marienbad, the cost of living is considerably cheaper than in the equivalent English spas or seaside places, whilst the scenery and the variety of the peasant population, the old-fashioned costumes, and quaint customs and habits of the rural inhabitants which are to be met with everywhere, in spite of the tendency to uniformity produced by modern education, form a pleasant change for those who are not used to it. There are four distinct groups of kurorte in Austria, with four different groups of indications. One group, mostly situated in the northern parts of Bohemia and Silesia on the slopes and within the northern valleys of the Bohemian mountains, comprises the spas with warm medicinal springs, the principal names being Carlsbad, Marienbad, Franzensbad, and Teplitz-Schönau. Another group, where the clear, pure mountain air is the chief factor or where the warm, mild climate is sought on account of the position in a warm valley, comprises the well-known places in the Tyrol—Meran, Bozen, Gries, Arco, and Riva; these places give excellent results in cases of diseases of the upper and lower air passages. The next group is formed by those kurorte which possess special mineral waters containing sulphur, iodine, iron, or alkalies, such as Baden, Darkau, and Hall, whilst a number of health resorts situated on the sea coast, or within the Alpine region, are famous simply for the tranquillising effect of their bracing, healthy climate. Of all these places the Bohemian mineral springs are the best known. It is unnecessary to speak of

Carlsbad and Marienbad in this article. They are well known o all English readers; but the other place, Franzensbad, deserves to be remembered by all medical men. The place tself is situated on the slopes of the Erzgebirge, protected against the northern winds and surrounded by extensive forests, and is arranged like a garden city. The springs are 12 in number: the waters are pure, of a somewhat acid taste, and with a trace of common salt and iron in them. The springs also contain a large amount of carbonic acid gas, which has lately become very important in rendering the waters a remedy for cardiac troubles if applied in the form of carbonic acid baths. The chief constituents of the waters are: sulphates of sodium and potassium, common salt, carbonates of magnesium, lithium, calcium, and sodium, and carbonate of iron, of which last constituent there are about 5 parts in 10,000 parts of the water. The Franzensbad waters are therefore among the strongest natural ferruginous waters. The quantity of free carbonic acid gas varies between 830 and 1800 cubic centimetres per litre of the water and the temperature is about 10° C. The carbonic acid contained in the water constitutes the chief factor of the modern development of this spa. Since the salutary qualities of carbonic acid baths have been made use of in the Nauheim treatment it has been claimed that Franzensbad, by the combination of its walks and promenades situated on a gentle slope, together with its effervescent baths, is at least equal to Nauheim, if it does not surpass it. A number of physicians have also settled here and the therapeutic results obtained are very good. The older indications of treatment at Franzensbad were anæmia and other disordered states of the blood, diseases of females, and chronic arthritic changes, which are treated here with the famous "Moor," or mineral mud, which forms an immense natural deposit amounting to about 6,000,000 cubic metres. Moor consists of a mixture of decomposed organic matter from swamps and ditches, with an admixture of alkaline substances, sulphuric, formic, and acetic acids, the result of decomposition in the absence of atmospheric oxygen. As prepared for therapeutic use it has the appearance of a thick, unctuous, brown mud. The number of visitors is upwards of 11,000 and the season lasts from the middle of April to the middle of October.

The second kurort belonging to the same geological formation is Teplitz-Schönau in Austria (Bohemia). The town has about 30,000 inhabitants and is one of the richest communities in the richest crownland of the Austrian Empire. The warm springs have been celebrated for 1100 years and belong to the class of alkaline-saline waters. Their temperature varies from 28° to 46° C. and their track has been discovered along the primary formation of the mountain range called Erzgebirge (metalliferous mountains). These ranges consist chiefly of porphyry, granite, and gneiss, and together with the basalt formation of the Mittel-Gebirge, they form beautiful landscapes with far-reaching plateaus and peaks, the stony soil of which is unsuitable for tree growth, so that extensive woods exist in only a few places. A notable fact in the history of the springs is that the flow of water ceased on two occasions. The first was in 1755, when the fearful earthquake of Lisbon occurred; the water suddenly ceased to flow but returned after a short time with more than its former force. After this the flow continued till in 1879 some coalmines in the vicinity of the spa were flooded by hot water and the springs again failed. Fortunately, however, for the watering-place, another and a larger supply was found at a somewhat greater depth than before. The chief constituents of the springs are sulphates of potassium and sodium, carbonates of iron, magnesium, lithium potassium, and strontium, alumina, and silicic acid. The diseases in which the waters of Teplitz-Schönau are indicated are rheumatism, gout, metallic poisoning, neuralgia, and catarrhal conditions of the uropoietic system. The curative effects of the waters are augmented by applications of mineral mud (Moor). The number of visitors who went there for medical treatment last year was 36,000.

A different series of indications characterises the so-called luft-kurorte (climatic health resorts) of the Tyrol and the Alps. These places are admirably suited for patients who either require a uniform mild climate without any violent changes of the temperature or air currents, or who are simply convalescents seeking quietness. They are situated chiefly in the middle of the large valleys in the Alps. One of them is Ischl in the Salzkammergut near Salzburg. The town is situated in the centre of the picturesque district, which comprises upon a comparatively small area a beautiful specimen of Alpine scenery, including half a dozen lakes and seas, as well as mountains covered with perpetual snow up to 5000 feet high. The kurort is sheltered from the north and west winds by the lofty wooded peaks of the Traungebirge, and the climate is very mild and moist. The number of days with rain or snow is about 178 per annum, and the mean temperature is 8° C. The therapeutic agents are, besides the air, the saline-alkaline waters and the so-called quell-soole, or salt brine. The springs are cold, pure, and contain chloride of sodium and carbonate of calcium, whilst the "soole" is a concentrated (25 per cent.) solution of the salt found in the mountains. These latter contain in many places salt mines which are made use of by flooding them with water. This water dissolves out all the salt, then it is conducted by means of a great aqueduct into the baths, whilst another line of pipes brings the solution into the "Sudhaus" where it is evaporated so that the salt is obtained in a crystalline mass. The diseases suitable for treatment at Ischl are chlorosis, anæmia, general debility, chronic catarrhs of the upper air passages, and scrofulosis. Especially for the last diathesis the stay in Ischl with the use of the brine bath is much recommended. Very beautiful excursions into the Alpine surroundings and the bracing air of the lakes bring every year many thousands of visitors here.

A similar position as regards the advantages of the air and the water is attributed to a small place called Vöslau, about 20 miles to the south of Vienna. The place itself is a quiet modern garden village which boasts of the purest akratothermal spring (28° C.) in Europe. A very large swimming establishment is supplied by this spring; its water is so clear that even at the depth of four metres each pebble is visible. Good results have been obtained from the external use of it in cases of anæmia and in rachitic children, whilst the "grape cure," consisting in the consumption of increasing quantities (from one to six pounds daily) of the fine Vöslau grapes is a speciality of the place in September. Lovely scenery of a subalpine character may be enjoyed from any house in the village.

Semmering is a name which has come into prominence only lately, but which indicates first-class air of a bracing character free from every trace of dust. It is situated at an altitude of 1000 metres (3000 feet), opposite the peaks of the Schneeberg and Rax which are 5000 feet high. This is reached in two hours by train from Vienna and has quickly obtained a well-founded reputation as a resort for convalescents. But the place is quickly losing its rural character on account of the accommodation (excellent in its way) provided there by an enterprising company.

As regards places in the Tyrol, they are already well known in English circles, at least Meran and Bozen. Of these two the first is a health restorer *par excellence* for diseases of the air passages, especially for the early stages of pulmonary tuberculosis. It occupies a commanding position in the valley of the Texel and Iffinger, is about the centre of the Tyrol, and faces the south, whilst it is sheltered in all other directions by the before-named mountains, which are from 6000 to 7000 feet high. The peculiarities of its climate are its elevated position (1500 feet above sea-level), great purity of the air and absence of clouds. During the winter months (November to March) there were 55 absolutely cloudless days, so that only Cairo beats it in this respect (63 days), and in Meran rain fell on only 45 days and snow on only seven days during the year, whilst all other climatic resorts (except Cairo) show a larger number of days with rainfall. The air is very tranquil, there being only 14 days of high wind in winter, and its relative humidity is 68 per cent., like Davos, Cairo, and the Riviera. Patients may therefore spend the greater part of the day out of doors. The temperature hardly ever goes below 0° C. in the winter at noon. Moreover, there are provided all apparatus for inhalation, vapourisation, and electric and gymnastic treatment. The indications are clear: incipient pulmonary tuberculosis, weakly children, chronic exudations, inflammations of the glands, and nervous debility. Prices are not high, so that a person may live here on £10 10s. a month pretty comfortably. The situation of Meran in the centre of the Tyrol marks it as a starting-point for tourists and the beauties of the Alps are easily enjoyed. The number of English visitors was upwards of 700 last year, whilst 17,000 persons were counted during the season which lasts from September to June.

Similar conditions prevail in Bozen and Gries, two places which are not far away, and where the climatic conditions are nearly the same. The only difference is perhaps to be seen in the fact that the last-named two places are more frequented by patients, whilst Meran has other visitors as well. In all the Tyrol towns there are picturesque houses and old-fashioned habits and the hospitality of the population is too well known to require special mention. Also in the south of the Tyrol—namely, on the Italian frontier—there are a number of health resorts which are not very much known outside the empire, but which deserve to be mentioned in this article. Arco, Riva, and Rovereto are the three most important of them. The climate is that of the north of Italy—very warm and dry—and the presence of the large Lake Garda brings the influence of this great expanse of water to bear upon the air, so that a stay in one of these places, or in Torbole, Mori, and Salo, is very often recommended to convalescents. The latter names are known to all tourists in the Tyrol and North Italy, for the scenery can scarcely be surpassed in grandeur and beauty. The prices are low, the water is good, and the sanitation is now improved. At the height of the season accommodation is somewhat scarce. As regards the language, German is sufficient even in the Italian parts of the Tyrol, whilst English is at least understood in all the places, because numerous visitors go to the Alpine countries from England and America, and they are welcome guests. The money is Austrian currency throughout, and meals are mostly arranged on the continental system of breakfast, dinner at noon, tea, and supper after 7 P.M.

Among the kurorte with special waters mention may be made of the sulphur springs of Baden, the arsenical waters of Levico, and the springs of Hall and Darkau containing salts of iodine and bromine. The first-named of these places, Baden, lies 20 miles to the south of Vienna, and is in summer, during the season, the favourite health resort of the well-to-do-classes of the capital. The mineral springs, 13 in number, are very old, inasmuch as the ancient Romans are said to have derived benefit from them. The principal saline constituents of the springs are the sulphates of iron, aluminium, and calcium, and by the interaction of the atmospheric oxygen and the sulphuretted water pure sulphur is set free in a state of suspension in the water, giving it a beautiful bluish appearance. The temperature of the springs varies from 28° to 40° C., and a large swimming-bath, with the sulphur water of 26° C., is a feature of the place. Rheumatic affections and the gouty and arthritic diathesis are much benefited by the external application of the waters in combination with the sulphur mud; in recent years the sulphuretted water has been discovered to be radio-active. Diseases of the skin attended with desquamation (eczema, psoriasis, and seborrhœa) are successfully treated here. The lovely neighbourhood of Baden, at the opening of the Helenenthal, and the excellent accommodation combine to make the place one of the most frequented kurorte in Austria. The number of visitors paying kurtaxe was 30,000 last year. The only drawback for some people is the peculiar smell of sulphuretted hydrogen exhaled by the waters at their source.

The arsenical waters of Levico are now employed by many physicians in Germany, France, and Italy. The place itself lies in the south of the Tyrol, has 2000 inhabitants, and possesses three springs yielding medicinal waters. These contain arsenic, iron, and copper, mostly as carbonates and hydroxides. The water is only used for drinking and is exported in bottles to all parts of the world. Anæmia, chlorosis, diseases of females, arterio-sclerosis, and cachexia are the principal indications for a visit to Levico. The place is quite modern; although small, the number of visitors was 3000 in 1905, and the season lasts practically all the year round, as the climate is actually that of a warm southern place.

Next in order come the iodine waters. There are two places famous for their springs. The one is Darkau in Silesia, the waters of which are said to be the strongest in Europe. The two springs are very old, and one is 750 metres deep, whilst the other is only 90 metres deep. The quantity of mineral water obtained from both these is more than 20,000 litres per day. They contain in 10,000 parts of water 0·130 parts of silica, 151 of chlorine, 1·021 of bromine, 0·395 of iodine, and 114 of soda, as well as oxide of iron, sulphuric acid, potash, and organic matter. Darkau is the only place where the iodine waters are strong enough for bathing and not too strong for drinking. The temperature of the water is 7° C., and the water comes from tertiary formations through layers of salt, gypsum, and granite. It has a peculiar taste and smell, and it is used in all affections where iodine compounds are indicated, especially scrofulosis, syphilis, and goitre. The place is famous for its cheapness and for the colonies of children sent thereto from all parts of the empire. A stay of four weeks, together with 25 baths and medical attendance and the kurtaxe, is easily covered by £10 or £12.

Bad Hall, in Upper Austria, the rival of Darkau, is a very well-known health resort with the same indications but with weaker waters. There are four springs in the town, of a temperature of 11° C., and producing nearly 100,000 litres per day, which are also exported all over the world in bottles. The water contains in 10,000 parts 0·26 parts of iodine, 0·71 of bromine, and 79·6 of chlorine, as well as sulphuric acid, magnesia, ferric compounds, and carbon dioxide. The waters are used both internally and externally, being not only drunk but also employed for "inhalation," gargles, and fomentations. The number of visitors in 1905 was 1800. The diseases specially suitable for treatment are syphilis and tuberculosis but the excellent country-life opportunities are beneficial also to persons suffering from nervous diseases, anæmia, and hysteria, as well as to those afflicted with exudations into different cavities.

The marine resorts of Austria are all situated on the coast of the Adriatic sea, which is warm and seldom stormy. The water is nearly as concentrated as that of the Baltic sea, whilst the kurorte are quaint small places with Eastern characteristics; Greek, Italian, Turkish and other Oriental features may be seen at every step. Sea-bathing goes on from April to November, as the temperature of the sea varies from 20° to 32°C. (68° to 90° F.), according to the time of the year, and sun and air baths are to be had during five months. The places are invariably ancient relics with modern patches in them. Their early history records many cruel wars or savage devastations by invading Goths or Huns, whilst Venice found one source of its wealth and power in the rich countries on the east of the Adriatic. Now they are parts of the Austrian Empire. A succession of fine harbours begins at Abbazia and reaches as far as Cattaro, with 25 islands lying off the mainland. The name of the country is Dalmatia and the population a mixed race of Slavs, Celts, and Romans. Living is very cheap there and the number of visitors is ever increasing. Then there is Abbazia, which possesses relics 1500 years old, and whose bishops were once rivals of the Pope. The promenade along the sea front is six kilometres in length, and beautiful sands, together with the absence of violent changes in the weather, combine to make it a first-class seaside resort for the anæmic and the neurotic; 20,000 visitors were counted in 1904, amongst them being the Emperor William II. of Germany. There is also Grado, facing south, which with miles of sand and with hours of brilliant sunshine is an ideal place for children. Grado has the best record of sunshine in Austria and is one of the warmest places on the coast. Ancient churches with gravestones from the year 530 prove the age of the town; the concentrated sea-water is very good for scrofulosis and has been known and employed for this purpose ever since that time. Then there are Loorana, Lussin, and Brioni, the last like the Isle of Wight, with a mild, somewhat moist climate and good accommodation, but a little out of the way of the general traffic. In fact, all the watering places of Dalmatia are only beginning to come to the notice of the medical profession as health resorts, but they have a good future before them, for the opportunities which they offer in respect to quiet, climate, influence of the sea, and the sub-tropical outdoor life are not to be found in the fashionable kurorte.

BRITISH MEDICAL BENEVOLENT FUND.

AT the last monthly meeting of the committee 13 applications for assistance were received and sums amounting to £104 were voted in relief to 11 of the cases. Two vacant annuities of £20 were filled by the election of candidates from the selected list. An abstract of the cases to which help was given is appended.

1. M.D. (Aberdeen), aged 54 years. Used to practise in London but was obliged to give up a few years ago and is now making a fresh start in the country. Is promised some help by a friend. Two children, the younger at school. Voted £10.

2. Widow, aged 46 years, of M.D. (Glasg.). Only income a few shillings a week. Two children, aged five and three years. Voted £10.

3. Widow, aged 56 years, of L.R.C.P. Edin. Income £10 a year;

slight help from sons. Is endeavouring to obtain a post as housekeeper or companion but finds great difficulty. Voted £5.

4. Widow, aged 52 years, of M.D. Aberd. No income; health very feeble. Two children, but unable to help. Voted £10.

5. Widow, aged 47 years, of M.R.C.S. No income; endeavours to support herself by letting lodgings. A son unable to work owing to ill health. Voted £12.

6. Daughter, aged 59 years, of late M.R.C.S. Dependent on a Government pension of £14 a year and an annual gift from Lloyd's Patriotic Fund. Health indifferent. Relieved ten times, £70. Voted £5.

7. Daughter, aged 60 years, of late M.R.C.S. No income and mentally deficient. Relieved once, £12. Voted £12.

8. Daughter, aged 67 years, of late M.R.C.S. Only provision a small annuity. Relieved once, £5. Voted £5.

9. Daughter, aged 51 years, of late M.R.C.S. Has supported herself as a teacher but finds she can no longer obtain employment. Relieved once, £10. Voted £10.

10. Widow, aged 65 years, of late M.D. Edin. No income; children unable to help. Relieved three times, £37. Voted £12.

11. Daughter, aged 62 years, of late M.R.C.S. Has a pension of £20 a year. Unable to earn on account of indifferent health and failing sight. Relieved 12 times, £96. Voted £10.

Looking Back.

FROM

THE LANCET, *SATURDAY*, June 13th, 1829.

CASE OF AMNESIA.

It is a question yet to be *decided*, *whether* the intellectual and moral faculties have for their various modifications distinct organs, or have the brain as a common organ, in which the different faculties may be displayed. *This* question is to be mainly resolved, it is most probable, by a careful attention to the intellectual phenomena *in a morbid* state. In this view, the following case, it *appears to me*, is deserving to be placed on record:—

The Rev. Mr. R., ætat. 48, is of a sanguine temperament, tends to obesity, enjoys excellent health, his intellect of a high order, temper good, and lively. He has lately experienced some mental anxiety. Sept. 5th, 1828, he awoke *early with headach*, after a restless night. He had taken a sudden cold the previous evening. Some castor oil now exhibited acted freely, and he again laid down. At *eleven I was sent for suddenly*, and *found him* in bed, evidently in the full possession of his senses, but incapable of uttering *a word. There* was frontal pain over the eyes; the tongue was in *no* way affected. All my questions were perfectly comprehended, and answered by signs; and it could be plainly seen, by the *smile* on the countenance, after many ineffectual attempts to express his ideas, that he was himself surprised, and *somewhat* amused, at his peculiar situation. The face at this time was flushed, the pulse full and somewhat slow, and to my inquiries if he suffered pain in the head, he pointed to the front of his *forehead* as its seat. I directed hot water to be brought in a bucket, for a pediluvium, and made preparations to draw *blood*. Mr. R. exhibited at this time a strong desire to *speak*, *and*, after a great many ineffectual efforts, endeavoured to make me comprehend his meaning by signs. Finding I could not understand him, he made a sign that he would write. When *furnished* with pen and paper, he attempted to convey his meaning, but I saw he could not recall words, and that he had written *an unintelligible* phrase; it was "Didoes doo the doe." *Forty ounces of blood* were drawn from the arm, and before the *operation* was completed, speech was restored, though a difficulty *continued* as to the names of things, which could not be *recalled*. *The bleeding* and pediluvium produced some faintness, and he was placed in bed. The loss of speech appearing *to* recur again, in fifteen minutes, ten ounces more of blood were abstracted, and sinapisms applied to the arms, legs, and thighs, *alternately*: the skin became moist, and the headach was *relieved*. Mr. R. now communicated to me, that when he made the attempt to write, he had intended to inform *me he* had already used a foot bath, and I might see the floor still wet, where the water had been spilt. The sleep that *night* was disturbed by *uneasiness* and throbbing in the head, which disappeared in the *course* of *the 6th*, and no further return of the affection has occurred.

The inference to be drawn from these facts are, 1st. That as the cerebral irritation produced no general affection or disturbance of the functions of the *brain*, it was local or limited: and, 2d, as loss of language was the only functional derangement of the intellectual *faculties*, that faculty must have been connected with the portion of the brain, the seat of the irritation; and 3d. That an organ of language exists in the brain. This case lends a strong confirmation to the general truth of the doctrines of Phrenology. —*Dr. S. Jackson, Pennsylvania.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS

In 76 of the largest English towns 6316 births and 4213 deaths were registered during the week ending June 8th. The annual rate of mortality, which had been equal to 15·1, 14·0, and 14·5 per 1000 in the three preceding weeks, further declined to 13·7 in the week under notice. During the first ten weeks of the current quarter the death-rate in these towns has averaged 15·7 per 1000, the rate in London during the same period being 15·2. The lowest annual death-rates in the 76 towns during the week were 4·9 in Burton-on-Trent, 5·9 in Barrow-in-Furness, 7·0 in Walthamstow, and 7·5 in Hornsey; the highest rates were 20·5 in Middlesbrough, 23·1 in St Helens, 23·6 in Huddersfield, and 23·8 in Tynemouth. The 4213 deaths in the 76 towns showed a further decrease of 223 from the steadily declining numbers in recent weeks, and included 463 which were referred to the principal epidemic diseases, against 474 in each of the two preceding weeks; of these, 193 resulted from measles, 130 from whooping-cough, 49 from diarrhœa, 48 from diphtheria, 30 from scarlet fever, 13 from "fever" (principally enteric), and not one from small-pox. The deaths from these principal epidemic diseases were equal to an annual rate of 1·5 per 1000, the rate from the same diseases in London being 1·6. No death from any of these epidemic diseases was registered last week in Plymouth, Stockport, Rochdale, Devonport, Hastings, Rotherham, Barrow-in-Furness, or Stockton-on-Tees; the annual death-rates therefrom, however, ranged upwards to 3·0 in Portsmouth, 3·1 in Hanley, 3·7 in Bolton, 4·1 in Wigan, 4·2 in Tottenham, and 5·6 in Middlesbrough. The fatal cases of measles, which had been 214, 207, and 201 in the three previous weeks, decreased to 193 in the week under notice; the highest death-rates from this disease were 1·9 in Blackburn, 2·1 in Gateshead, 3·1 in Hanley and in Bolton, and 5·1 in Middlesbrough. The 130 deaths from whooping-cough were in excess of the numbers in the two preceding weeks; the annual death-rates from this cause ranged upwards to 1·3 in Tottenham and in Newcastle-on-Tyne, 1·4 in South Shields, 1·6 in Walsall and in Wallasey, and 1·9 in Tynemouth. The deaths referred to diarrhœa, which had been 61, 51, and 47 in the three previous weeks, were 49 last week. The 48 fatal cases of diphtheria corresponded with the number in the preceding week; the mortality was highest in Portsmouth, Reading, and Norwich, being equal in each case to an annual rate of 1·3 per 1000. Of the 30 deaths from scarlet fever, 11 occurred in London, four in Liverpool, and one in each of 15 other towns; while the 13 cases of "fever" included three in London, two in Manchester, and one in each of eight other of the 76 towns. The number of scarlet fever cases in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2679, 2732, and 2824 at the end of the three preceding weeks, had further risen to 2861 at the end of the week under notice; 368 new cases were admitted *during* the week, against 383, 382, and 437 in the three preceding weeks. The deaths in London referred to pneumonia and other *diseases of the* respiratory organs, which had been 235, 230, and 192 in the three preceding weeks, further declined to 186 last week, but were 14 in excess of the number in the corresponding weeks of the five preceding years. The causes of 41, or nearly 1 per cent., of the deaths registered during the week were not *certified either* by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, *Bristol*, West Ham, Newcastle-on-Tyne, and in 50 other of the 76 *towns*; *the proportion* of uncertified deaths, however, again showed a *marked* excess in Liverpool, Birmingham, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, *which had been* equal to 19·7 17·5, and 16·7, per 1000 in the three preceding weeks, rose again to 19·0 in the week ending June 8th, and exceeded the rate in the 76 English towns by 5·3. The rates in the are nearly the same. The only difference is perhaps to be seen in the fact that the last-named two places are more frequented by patients, whilst Meran has other visitors as well. In all the Tyrol towns there are picturesque houses and old-fashioned habits and the hospitality of the population is too well known to require special mention. Also in the south of the Tyrol—namely, on the Italian frontier—there are a number of health resorts which are not very much known outside the empire, but which deserve to be mentioned in this article. Arco, Riva, and Rovereto are the three most important of them. The climate is that of the north of Italy—very warm and dry—and the presence of the large Lake Garda brings the influence of this great expanse of water to bear upon the air, so that a stay in one of these places, or in Torbole, Mori, and Salo, is very often recommended to convalescents. The latter names are known to all tourists in the Tyrol and North Italy, for the scenery can scarcely be surpassed in grandeur and beauty. The prices are low, the water is good, and the sanitation is now improved. At the height of the season accommodation is somewhat scarce. As regards the language, German is sufficient even in the Italian parts of the Tyrol, whilst English is at least understood in all the places, because numerous visitors go to the Alpine countries from England and America, and they are welcome guests. The money is Austrian currency throughout, and meals are mostly arranged on the continental system of breakfast, dinner at noon, tea, and supper after 7 P.M.

Among the kurorte with special waters mention may be made of the sulphur springs of Baden, the arsenical waters of Levico, and the springs of Hall and Darkau containing salts of iodine and bromine. The first-named of these places, Baden, lies 20 miles to the south of Vienna, and is in summer, during the season, the favourite health resort of the well-to-do-classes of the capital. The mineral springs, 13 in number, are very old, inasmuch as the ancient Romans are said to have derived benefit from them. The principal saline constituents of the springs are the sulphates of iron, aluminium, and calcium, and by the interaction of the atmospheric oxygen and the sulphuretted water pure sulphur is set free in a state of suspension in the water, giving it a beautiful bluish appearance. The temperature of the springs varies from 28° to 40° C., and a large swimming-bath, with the sulphur water of 26° C., is a feature of the place. Rheumatic affections and the gouty and arthritic diathesis are much benefited by the external application of the waters in combination with the sulphur mud; in recent years the sulphuretted water has been discovered to be radio-active. Diseases of the skin attended with desquamation (eczema, psoriasis, and seborrhœa) are successfully treated here. The lovely neighbourhood of Baden, at the opening of the Helenenthal, and the excellent accommodation combine to make the place one of the most frequented kurorte in Austria. The number of visitors paying kurtaxe was 30,000 last year. The only drawback for some people is the peculiar smell of sulphuretted hydrogen exhaled by the waters at their source.

The arsenical waters of Levico are now employed by many physicians in Germany, France, and Italy. The place itself lies in the south of the Tyrol, has 2000 inhabitants, and possesses three springs yielding medicinal waters. These contain arsenic, iron, and copper, mostly as carbonates and hydroxides. The water is only used for drinking and is exported in bottles to all parts of the world. Anæmia, chlorosis, diseases of females, arterio-sclerosis, and cachexia are the principal indications for a visit to Levico. The place is quite modern; although small, the number of visitors was 3000 in 1905, and the season lasts practically all the year round, as the climate is actually that of a warm southern place.

Next in order come the iodine waters. There are two places famous for their springs. The one is Darkau in Silesia, the waters of which are said to be the strongest in Europe. The two springs are very old, and one is 750 metres deep, whilst the other is only 90 metres deep. The quantity of mineral water obtained from both these is more than 20,000 litres per day. They contain in 10,000 parts of water 0·130 parts of silica, 151 of chlorine, 1·021 of bromine, 0·395 of iodine, and 114 of soda, as well as oxide of iron, sulphuric acid, potash, and organic matter. Darkau is the only place where the iodine waters are strong enough for bathing and not too strong for drinking. The temperature of the water is 7° C., and the water comes from tertiary formations through layers of salt, gypsum, and granite. It has a peculiar taste and smell, and it is used in all affections where iodine compounds are indicated, especially scrofulosis, syphilis, and goitre. The place is famous for its cheapness and for the colonies of children sent thereto from all parts of the empire. A stay of four weeks, together with 25 baths and medical attendance and the kurtaxe, is easily covered by £10 or £12.

Bad Hall, in Upper Austria, the rival of Darkau, is a very well-known health resort with the same indications but with weaker waters. There are four springs in the town, of a temperature of 11° C., and producing nearly 100,000 litres per day, which are also exported all over the world in bottles. The water contains in 10,000 parts 0·26 parts of iodine, 0·71 of bromine, and 79·6 of chlorine, as well as sulphuric acid, magnesia, ferric compounds, and carbon dioxide. The waters are used both internally and externally, being not only drunk but also employed for "inhalation," gargles, and fomentations. The number of visitors in 1905 was 1800. The diseases specially suitable for treatment are syphilis and tuberculosis but the excellent country-life opportunities are beneficial also to persons suffering from nervous diseases, anæmia, and hysteria, as well as to those afflicted with exudations into different cavities.

The marine resorts of Austria are all situated on the coast of the Adriatic sea, which is warm and seldom stormy. The water is nearly as concentrated as that of the Baltic sea, whilst the kurorte are quaint small places with Eastern characteristics; Greek, Italian, Turkish and other Oriental features may be seen at every step. Sea-bathing goes on from April to November, as the temperature of the sea varies from 20° to 32°C. (68° to 90° F.), according to the time of the year, and sun and air baths are to be had during five months. The places are invariably ancient relics with modern patches in them. Their early history records many cruel wars or savage devastations by invading Goths or Huns, whilst Venice found one source of its wealth and power in the rich countries on the east of the Adriatic. Now they are parts of the Austrian Empire. A succession of fine harbours begins at Abbazia and reaches as far as Cattaro, with 25 islands lying off the mainland. The name of the country is Dalmatia and the population a mixed race of Slavs, Celts, and Romans. Living is very cheap there and the number of visitors is ever increasing. Then there is Abbazia, which possesses relics 1500 years old, and whose bishops were once rivals of the Pope. The promenade along the sea front is six kilometres in length, and beautiful sands, together with the absence of violent changes in the weather, combine to make it a first-class seaside resort for the anæmic and the neurotic; 20,000 visitors were counted in 1904, amongst them being the Emperor William II. of Germany. There is also Grado, facing south, which with miles of sand and with hours of brilliant sunshine is an ideal place for children. Grado has the best record of sunshine in Austria and is one of the warmest places on the coast. Ancient churches with gravestones from the year 530 prove the age of the town; the concentrated sea-water is very good for scrofulosis and has been known and employed for this purpose ever since that time. Then there are Locrana, Lussin, and Brioni, the last like the Isle of Wight, with a mild, somewhat moist climate and good accommodation, but a little out of the way of the general traffic. In fact, all the watering places of Dalmatia are only beginning to come to the notice of the medical profession as health resorts, but they have a good future before them, for the opportunities which they offer in respect to quiet, climate, influence of the sea, and the sub-tropical outdoor life are not to be found in the fashionable kurorte.

BRITISH MEDICAL BENEVOLENT FUND.

AT the last monthly meeting of the committee 13 applications for assistance were received and sums amounting to £104 were voted in relief to 11 of the cases. Two vacant annuities of £20 were filled by the election of candidates from the selected list. An abstract of the cases to which help was given is appended.

1. M.D. (Aberdeen), aged 54 years. Used to practise in London but was obliged to give up a few years ago and is now making a fresh start in the country. Is promised some help by a friend. Two children, the younger at school. Voted £10.

2. Widow, aged 46 years, of M.D. (Glasg.). Only income a few shillings a week. Two children, aged five and three years. Voted £10.

3. Widow, aged 56 years, of L.R.C.P. Edin. Income £10 a year;

London, and that it does not propose to abandon the teaching of the preliminary and intermediate subjects under these circumstances."

I am to add that this decision must not be construed as adverse to the principle of the concentration of the preliminary and intermediate medical studies in the University, but solely as directed against the particular proposals for concentration indicated in the resolution.

Believe me, Sirs, yours faithfully,
June 11th, 1907. HERBERT L. EASON, Dean.

A SOCIETY FOR THE PREVENTION OF VENEREAL DISEASES.

To the Editors of THE LANCET.

SIRS,—*Will you kindly allow me to ask your correspondent*, "H. N. R.," if he has read the report of the Departmental Committee of the Local Government Board on the deterioration of public health? Has he also read the many articles, annotations, and letters which have appeared in your columns showing the inadequacy of hospital accommodation for venereal diseases throughout the whole of the United Kingdom? Consideration for your space induces me to ask him to send me his name and address; I can then send him additional information which he may find useful.

I am, Sirs, yours faithfully,
FRED. W. LOWNDES.
42, Knight-street, Liverpool, June 11th, 1907.

THE HOSPITAL FUNDS AND THE EXCLUSION OF SCOTTISH DIPLOMATES FROM THE MAJORITY OF LONDON HOSPITALS.

To the Editors of THE LANCET.

SIRS,—*On behalf of the council of the Association of Medical Diplomates of Scotland I beg to draw your attention* to what we consider a grave injustice to those holding the diploma of the Scottish colleges. We refer to the clause in the laws of many medical charities of the metropolis making the possession of a London qualification an essential condition of election to a post on the honorary medical and surgical staffs. The effect is to make those posts a monopoly in the hands of certain London corporations. We submit that this practice inflicts a gratuitous injury upon the diplomates of the Scottish colleges who have obtained their legal qualifications after stringent examination. We submit that the exclusion of which we complain is contrary to the elementary grounds of justice and that its result, if not its intention, is to swell the ranks and to increase the revenues of certain London corporations at the expense of rival colleges, of Scottish diplomates, and, as we think, of the community in general. This arbitrary practice is, in our opinion, a *relic of class* privilege absolutely out of touch with the trend of modern thoughts and ideas and one calculated to close the door to many a fine career and in the long run to inflict injury upon the public by narrowing the field of competition. If the London qualification be of such supreme excellence why should their holders fear competition in the open market? Why resort to such a weapon as disqualification of all Scottish and Irish competitors? This exclusion of Scottish diplomates from the majority of London and provincial hospital appointments has been going on for many years. Our present object, however, is to draw attention to its revival in an insidious form and its imposition by a side issue upon two institutions that previously welcomed Scottish diplomates to their honorary staffs. *We wish to show how the Hospital* Sunday and King Edward's Funds have helped, doubtless unwittingly, to bring about that injustice.

There were lately three London orthopædic *hospitals*—the Royal, the City, and the National. The above-mentioned funds have for some years *pressed the* policy of amalgamation upon these hospitals by every *means in their* power. Of these three hospitals the Royal and the City admitted Scottish diplomates to *their staffs*, while the National excluded them. All three institutions are now amalgamated. It *seems incredible* that the funds should have permitted the new charter of the consolidated *hospitals* to exclude Scottish diplomates. Such, however, has been the *case. In* other words, the National Orthopædic Hospital has been enabled to force its exclusiveness upon *the other* two partners in the new institution. One holder of a *Scottish* qualification has been allowed to join the new staff, apparently in defiance of the charter. Another *member of the City Orthopædic has been denied any staff appointment* in the new institution on the ground of not possessing a higher English qualification. That gentleman naturally protested against his exclusion. To investigate the facts of the case Sir Edmund Hay Currie was appointed arbitrator. His report stated that: (1) the charter could be amended; (2) that an exception should be made in favour of the gentleman concerned; and (3) that the conditions as to qualification would doubtless be retained in the new charter.

We submit, Sirs, that this charter in its present form is unjust, inasmuch as it excludes Scottish diplomates. We submit further that its amendment should be made to cover not only the specific hard case of a single Scottish diplomate but to throw open all staff appointments to all registered medical practitioners.—*I am, Sirs, yours faithfully*,

CLAUDE ST. AUBYN-FARRER, President.
Charles-street, W., May 31st, 1907.

THE ESTIMATION OF SUGAR.

To the Editors of THE LANCET.

SIRS,—An annotation in THE LANCET of May 25th describes Swietecki's method of ascertaining the amount of sugar in urine by the tint obtained by boiling with an alkali. This is, of course, a quantitative application of Moore's test. The method, in a much less elaborate form, which has been long available, deserves to be more widely known on account of its extreme facility. I worked it out with glucose many years ago and communicated it to Sir Lauder Brunton, who quoted it in his article on "Diabetes" in Reynolds's "System of Medicine," Vol. V., 1879, p. 395. *It is also given by Dr. R. W.* Leftwich in his "Index of Symptoms," third edition, and in Martindale's "Extra-Pharmacopœia." It enables an approximation to the amount of sugar to be obtained, without apparatus, in two minutes, and depends on the tint obtained on boiling *for 30 seconds* a mixture of equal parts of liq. potassæ and the urine. It is best observed by boiling the upper half of the mixture in a test-tube. If the mixture is still tinted the urine must (as you state) be decolourised, which is quickly done by filtering through paper on which a little animal charcoal has been sprinkled. The amount of sugar corresponds closely to the following simple tint scale. If lemon yellow, five grains per ounce; if pale sherry, ten grains; if dark sherry, 15 grains; if port wine colour, 20 grains per ounce and upwards. In the latter case it is necessary to dilute the urine with an equal part of water and repeat the process. I have often had a skilled analysis afterwards made and never found the amount differ much from the result obtained. I have tried to produce fixed colour standards, but the exactness obtainable seemed insufficient to compensate for the trouble. Not only is a precise comparison of tint difficult, but if the sugar is more than ten grains per ounce the colour is deepened unduly by too long boiling. No method of applying copper reduction to dilution can be made a practical speedy indication, but this quantitative use of Moore's test is a useful illustration of "the practical service of *imperfect* means."

It should not be forgotten that we owe the familiar "Moore's test" to a general *practitioner of Bourton-on-the* Water, Gloucestershire, who died not many years ago.

I am, Sirs, yours faithfully,
May 29th, 1907. WILLIAM R. GOWERS.

THE PROCEEDINGS AT THE RECENT MEETING OF THE GENERAL MEDICAL COUNCIL: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your report of the proceedings of the General Medical Council *of Thursday, May 30th*, in THE LANCET of June 8th, p. 1593, I am made out to have said that there is a lack of *opportunity* of obtaining midwifery cases for London students. *This is* a complete misunderstanding, as I opposed the resolution of Sir C. Ball to *reduce* the number *(20)* of cases of labour to be attended by each student; and I have never heard *that students* in London have had, or now have, the least difficulty in obtaining this number *of labours* to attend. *I said* that there was, and *would be for* some time, difficulty in obtaining *for the whole of* the students in London regular daily attendance upon the indoor practice of eight Scotch towns ranged from 17·2 in Edinburgh and 18·4 in Glasgow to 21·1 in Dundee and 29·9 in Perth. The 660 deaths in the eight towns showed an increase of 80 over the number in the previous week, and included 109 which were referred to the principal epidemic diseases, against 112, 92, and 91 in the three preceding weeks. These 109 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 1·6 the rate from the same diseases in the 76 English towns; they included 57 which were referred to whooping-cough, 26 to "fever," 13 to diarrhœa, seven to measles, four to diphtheria, two to scarlet fever, and not one to small-pox. The fatal cases of whooping cough, which had been 52, 39, and 38 in the three preceding weeks, rose again last week to 57, of which 37 occurred in Glasgow, seven in Dundee, four in Edinburgh and in Paisley, and two in Aberdeen and in Greenock. The deaths referred to "fever," which had been 41, 28, and 24 in the three preceding weeks, were 26 in the week under notice, and included 16 in Glasgow, five in Edinburgh, three in Leith, and two in Paisley; all these deaths, except one in Glasgow and one in Paisley, were certified as from cerebro-spinal meningitis. The fatal cases of diarrhœa, which had been seven, nine, and 14 in the three preceding weeks, decreased last week to 13, of which eight were registered in Glasgow, three in Dundee, and two in Aberdeen. The seven deaths from measles corresponded with the number in the preceding week and included five in Glasgow and two in Leith. Two of the four fatal cases of diphtheria occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had declined from 127 to 82 in the five preceding weeks, rose again to 106 last week, and were 11 in excess of the number in the corresponding week of last year. The causes of 28, or 4·2 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; the proportion of uncertified deaths in the 76 English towns during the same week did not exceed 1 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 26·7, 25·8, and 23·1 per 1000 in the three preceding weeks, rose again to 23·9 during the week ending June 8th. During the first ten weeks of the current quarter the death-rate has averaged 26·5 per 1000; the mean rate during the same period did not exceed 15·2 in London and 17·7 in Edinburgh. The 179 deaths of Dublin residents registered during the week under notice were six in excess of the number in the preceding week, and included 11 which were referred to the principal epidemic diseases, against seven, 17, and 13 in the three previous weeks; of these, six resulted from measles, four from whooping-cough, and one from diphtheria, but not any from small-pox, from scarlet fever, from "fever," or from diarrhœa. These 11 deaths were equal to an annual rate of 1·5 per 1000, the rate during the same period from the principal epidemic diseases being 1·6 in London and 1·5 in Edinburgh. The fatal cases of measles, which had been six and four in the two preceding weeks, rose again to six in the week under notice; while the deaths from whooping-cough, which has been ten and eight in the two preceding weeks, further declined to four. The 179 deaths from all causes in Dublin last week included 27 of children under one year of age and 47 of persons aged upwards of 60 years; the deaths of infants were slightly in excess of the number in the preceding week, while those of elderly persons showed a considerable decline. Five inquest cases and five deaths from violence were registered; and 71, or nearly two-fifths, of the deaths occurred in public institutions. The causes of two, or 1·1 per cent., of the deaths in Dublin last week were not certified; in London the cause of only one death was uncertified, while in Edinburgh the percentage of uncertified deaths was 7·9.. The 161 deaths registered in Belfast during the week under notice included 10 which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: W. H. Daw to Gibraltar Hospital; and E. F. Mortimer to the *Vindictive*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenant-Colonels retire on retired pay: George E. Twiss and John L. Hall (dated June 8th, 1907).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Charles Graham Grant to be Surgeon-Lieutenant-Colonel (dated May 28th, 1907). Surgeon-Major James Drummond, having been appointed to the command of the 3rd Durham Royal Garrison Artillery (Volunteers), ceases to belong to the Army Medical Reserve of Officers.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Captain (Honorary Captain in the Army) H. E. Mortis to be Major (dated April 24th, 1907).

CHANNEL ISLANDS MILITIA.

The Royal Militia of the Island of *Jersey*: Medical Company: Henry John Shone to be Surgeon-Lieutenant (dated May 25th, 1907).

VOLUNTEER CORPS.

Rifle: 1st Surrey (South London) Volunteer Rifle Corps: Surgeon-Lieutenant D. O. Kerr to be Surgeon-Captain (dated May 1st, 1907). 4th Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Supernumerary Surgeon-Lieutenant W. J. Woodman to be Surgeon-Captain, remaining supernumerary (dated May 2nd, 1907). 1st Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Lieutenant-Colonel W. H. Packer is granted the honorary rank of Surgeon-Colonel (dated April 20th, 1907). 1st Herefordshire Volunteer Rifle Corps: Surgeon-Lieutenant J. N. Macmullan to be Surgeon-Captain (dated Nov. 1st, 1906).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Scottish Command: Aberdeen Companies: Lewis Davie Cruickshank to be Lieutenant (dated May 7th, 1907).

The annual inspection of the London Companies of the Royal Army Medical Corps (Volunteers), as well as of the Bearer Companies of 1st, 2nd, 3rd, and 4th London Infantry Volunteer Brigades, by Colonel Sloggett, C.M.G., will take place in Hyde Park (Guards' Ground) on Saturday, June 15th, at 5.30 P.M. The proceedings are expected to have additional interest from the inclusion of a field ambulance station and a demonstration of carrying patients in cacolets.

THE GOVERNMENT'S NEW ARMY BILL.

It is a matter of such wide extent and importance as to be especially noteworthy that on June 10th the Territorial and Reserve Forces Bill was again considered and finally passed by the House of Commons in committee. The Earl of Wemyss had on the same day in the House of Lords asked a number of questions as to the army having a distinct bearing on the new scheme and had been replied to by the Earl of Portsmouth. In the course of the debate in the Commons a good many important points were raised by the Opposition on amendments which were, however, defeated and the guillotine resolution then came into operation. All the clauses and schedules were adopted and, as we have already said, the Territorial and Reserve Forces Bill was successfully passed through its final committee stage.

Correspondence.

"Audi alteram partem."

THE MEDICAL SCHOOL OF GUY'S HOSPITAL AND THE CONCENTRATION OF EARLY MEDICAL STUDY.

To the Editors of THE LANCET.

SIRS,—The following letter has been addressed by the treasurer of Guy's Hospital (Mr. Cosmo O. Bonsor) to the Principal of the University of London:—

> As treasurer of Guy's Hospital I have to bring to your notice the following resolution passed at a school meeting on the 7th inst. and approved by me: "That, in view of the resolution of June, 1905, that the Medical School of Guy's Hospital is not committed to any particular line of action with regard to the concentration of preliminary and intermediate studies, the school now desires the treasurer to inform the Senate of the University of London that it is of the opinion that the proposed scheme of three centres for the teaching of such subjects at University College, King's College, and South Kensington, and the institution of internal examinations at these centres, would not be to the advantage of medical education in

the further attempt to acquire 1167 square yards in the surely ironically named Oxygen-street, and two other plots, one in Communication-road and the other in Lawford-street, for the purpose of making playgrounds for children in much congested districts, will also be accomplished. The total sum required is £12,500, and £7750 have already been promised. This includes two sums of £1000 each promised by the Smethwick town council and the Handsworth district council towards the purchase of the Black Patch which will be of great value to both districts as well as to Birmingham. Our city at present is woefully devoid of breathing spaces in its thickly populated areas but the activity of the young but very vigorous Open Spaces Society seems likely to change matters for the better in a comparatively short space of time.

The Crippled Children's Union.

The chairman of the union, Mr. Montgomery Hooper, was in a justifiably optimistic humour when he presented the annual report at a recent meeting, for the previous year's deficiency of £264 had been reduced to £33, and the work of the union had been dealt with in the usual way. Apparently one of the chief difficulties which the society has to face is that of making adequate provision for these cases which require a long period of treatment in the country, but it is intended to make a special appeal on behalf of these cases. The directors of the union desire, if possible, to establish a convalescent home capable of dealing with about 40 children. They already possess a site, but they are considering the advisability of selling it and acquiring another at a higher level. They calculate that they will require £5000 for the accomplishment of their desire and £3000 have already been given.

Birmingham Medical Mission.

Each year the ladies' committee of this deserving charity holds a sale of work for the purpose of adding to the too scanty funds of the mission, by means of which much suffering and sorrow are relieved. It was hoped that this year the sum realised would not be less than £250 The sale extended over two days. On the first day it was opened by Mr. Jowett and on the second by Dr. T. Stacey Wilson, and fortunately the result was better than the anticipation, for the total obtained was £278. This, after all, is but a small sum to be scattered over a very large area for the immediate relief of some of the suffering which is only too prevalent in our crowded areas.

Hospital Collections.

It is customary to make an annual Saturday collection in the West Bromwich and Oldbury districts in aid of the West Bromwich District Hospital. This year the sum collected in West Bromwich amounted to £928, or £9 more than last year, and in the Oldbury district £298 were collected which is also a slight advance on the collection of the preceding year.

Health of Handsworth.

In presenting his annual report Dr. R. A. Lyster, the medical officer of the Handsworth urban district, drew attention to the urgent necessity for the consideration of proper hospital accommodation and he pointed out the unsatisfactory position of the district should it be invaded by a serious epidemic. He also emphasised the unsatisfactory nature of the accommodation provided for the health department and he stated that the present staff was inadequate for the needs of the district. The death-rate for the year was 11·1, being slightly higher than in the preceding year, and the birth-rate was 22·6, as compared with 22·7 for 1905. The most satisfactory feature of the report was the low death-rate from tuberculous diseases, 0·86 per 1000, which is a lower rate for these diseases than the surrounding districts can show.

Health of Birmingham.

The death-rate of the city keeps in what may be considered a fairly satisfactory condition. Three weeks ago it was 14·6 per 1000, a week later it fell to 14·4, and last week it rose to 15·9. The only really unsatisfactory feature of our health at present is the continued prevalence of scarlet fever, measles, and diphtheria, in spite of all care and precautions. Last week the number of cases in the fever hospital decreased to 314 from 317, but it had risen in the previous week to the latter number from 312. The fluctuations are slight but the total number is greater than is desirable.

June 11th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Country Hospital for Chronic Diseases of Children.

Mr. Holbrook Gaskell has added to his many acts of philanthropy a splendid gift of £5000 to complete the fund for the building of the Liverpool Country Hospital for Children at Heswall. Mr. Gaskell has expressed a wish that in an appropriate manner it should be recorded in the hospital that the gift is in commemoration of the labours of Miss Sedgwick and Dr. C. J. Macalister in commencing and bringing to a successful issue the great work which has been the pioneer of similar institutions on the same principle. Mr. Gaskell has already presented to the hospital a memorial of the eminent services of Mr. Robert Jones in a fine operating theatre. The hospital has carried on its work since 1899 in temporary premises at West Kirby, and whilst wishing the Lord Mayor of London every success in emulating and even advancing upon what Liverpool has already accomplished it is mere justice to give Liverpool the credit of being the pioneer in the British Isles of the provision of an institution devoted to the care of crippled children. The predecessor of Liverpool in this matter was France. The United States ran Liverpool closely in following the French example. Dr. Macalister points out in a communication to the local press that more money is required to complete Liverpool's scheme. In response to the appeals of the committee, generous donors have contributed handsomely to the building fund. One gentleman, at his own expense, is building the administrative block at a cost of about £6000; an anonymous donor has given £5000, and many others have contributed largely; and now at Heswall the central and administrative blocks of what will probably be the finest children's hospital of its time in the kingdom are nearing completion. Dr. Macalister emphasises the fact that not one penny has been spent on useless ornamentation. The hospital building is extremely plain, but internally its construction is as perfect as thought and experience can make it. It will, when fully completed, accommodate 200 children and will be worthy of the city with which it is connected. The *Liverpool Daily Post and Mercury* points out that "the institution owes its existence almost as much to Mr. Holbrook Gaskell and Miss Gaskell as to Dr. Macalister and Miss Sedgwick. They warmly accepted the idea. They saw its distinctive excellence and its humane capabilities. Their devotion to it was steadfast. Their encouragement sustained its working promoters."

Civic Grant to the University of Liverpool.

The report of the Treasury Commissioners on the work of the University has just been issued and is most satisfactory. The Commissioners state that the University is performing its functions with efficiency. "It is a university in the fullest sense of the term, providing a broad and generous education on the older as well as on more modern lines." This statement must be pleasing to the city council, in that it assures it that its grant is well spent. The report deals with the excellence and quality of the research work which is carried on at the University. There is one suggestion made by the Commissioners which might with advantage be adopted by the city council. The Treasury makes its university grants for a period of five years, and it would be a great convenience if this practice were adopted by the city council. It would assure the University council of the amount of money at its disposal if the civic grant were made a quinquennial instead of an annual one. The annual income of the University is now £61,000 drawn from four sources. Over £17,000 a year are derived from endowments, £15,000 from students' fees, £2000 from annual subscriptions for various purposes, and £26,000 from public funds. About one-half of the public money comes from the Government; the other half is supplied by the corporations of Liverpool, Birkenhead, and Bootle, and the county councils of Lancashire and Cheshire. Over £11,000 are devoted annually to the maintenance of the buildings and the provision of service and equipment and materials for the scientific laboratories, and £6000 for scholarships and fellowships. The proposal to renew the annual grant of £10,000 to the University came before the city council at its meeting on June 5th and was carried *nem. con.* The report of the Treasury Commissioners appeared at an opportune time, considerably strengthening the hands a lying-in hospital, or the lying-in wards of a general hospital.—I am, Sirs, yours faithfully,

HENRY MORRIS,
Representative of the Royal College of Surgeons of England on the General Medical Council.
Cavendish-square, W., June 11th, 1907.

A REPUDIATION.

To the Editors of THE LANCET.

SIRS,—It has just come to my notice that reprints of an article I wrote recently have been circulated with a trade advertisement. This was done without my knowledge or consent, and I have already insisted upon its discontinuance. I should be much obliged if you would publish this in the next number of THE LANCET.

I am, Sirs, yours faithfully,
Edgbaston, Birmingham, June 8th, 1907. W. A. POTTS.

VALUE OF HIGH-FREQUENCY SPARK AS A LOCAL APPLICATION.

To the Editors of THE LANCET.

SIRS,—Dr. Morton's note on high-frequency current as a stimulant for the growth of hair is interesting. I may say that I first used high frequency to the scalp in June, 1902. The patient was a lady, about 30 years of age, who had some early osteo-arthritic changes in the small joints of the hand and came to me complaining of slight seborrhœic rash on the face and considerable thinning and falling of hair. The results were brilliant. A thick growth of hair of good quality ensued, but unhappily the same application failed afterwards in apparently similar conditions. Now and then I find it useful in cases of premature partial alopecia, but not where the baldness is complete. To the latter statement there is an exception in the case of alopecia areata, in which hair often grows rapidly under the influence of the high-frequency current. But then, it should be remembered, it responds equally well to other forms of electrical current that redden the scalp. I have not found the high-frequency current of much use in cases of universal alopecia, whereas the continuous current is often satisfactory and invaluable. This latter fact was pointed out to me by my friend and colleague, Dr. Arthur Harries, who has done much work with the continuous current.

It seems to me that there remains a great deal to be solved in the etiology and pathology of alopecia areata, and that to some extent the key may be found in the therapeutic effects of various forms of electrical treatment.

I am, Sirs, yours faithfully,
London, W., June 4th, 1907. DAVID WALSH.

PS.—I may add that the high-frequency current was applied by contact with a water-filled glass electrode and in area cases also by a metal electrode with an air gap.

SOME MORALISING ON THE WEATHER.

To the Editors of THE LANCET.

SIRS,—The proverbial uncertainty of the English climate may cause a recapitulation of the unpleasant effects which its vagaries bring about to seem the whipping of a jaded horse, but the recent lamentable behaviour of May as exposed in an interesting leading article in THE LANCET last week surely affords a sufficient text upon which to hang some such reflections, the more especially as at present her successor has shown no sign of repentance. It may perhaps seem especially a warning of supererogation again to insist on the extreme importance of going warmly clad in a season when there may be a difference of 20 degrees of temperature on consecutive days, but in spite of oft-repeated warning of ancient adages and modern medicine every early summer claims its toll of lives amongst those who have neglected to profit by them. It is obviously a difficult matter to regulate the underclothing to the exigencies of such weather as we have recently experienced, but the old rule is the safe one, to be prepared for the worst, even though it involves severe discomfort in the unforeseen event of a sudden day of sunshine. To all who have passed through an attack of influenza during the late winter this counsel is of vital importance, for they are especially liable to the unwelcome ministrations of the *pneumococcus*, and in persons predisposed to tuberculosis a month such as the last should prove a fertile time for the seed-sowing of that malady. The continuation of the various catarrhs that winter visits upon our mucous membranes is a less serious, but still a very unwelcome, result of the weather and is well worth guarding against.

But not the least of the ill-effects of a summer *manqué* is the moral one of starting day after day with a personal sense of irritation against the elements. Not even the egregious optimist who cheerily breaks the ice on the Serpentine for his December plunge greets a bleak and gusty day of June with approbation. The beginning of the day in this irritated state of mind must needs react upon the work that is to do. That work is more unwelcome, and set-backs in its accomplishment are doubly vexing, which is only another way of saying that it is harder and that to do the usual amount is accompanied with unusual fatigue. The medical practitioner knows that this is the state of mind and body which leaves a man susceptible to pathological attacks and woman no less so than man, while woman's particular work is much affected by a winterly summer. For in the domestic sphere the restarting of fires after the sweeping and garnishing incidental to spring cleaning proves a grave trial to the careful housewife rejoicing in her dustless carpets and cornices, or the no less careful parent who has stored away carefully all her children's winter clothes.

There are oft-repeated circumstances pointing to a relationship between unseasonable weather and suicide, but until the Registrar-General has spoken I do not know if any increase in the number of suicides can be adduced to justify this denunciation of the May just gone. But I shall be surprised to learn that medical practitioners have not found it their general experience that during the month minor ailments were more obstinate than usual against treatment, even when their etiology had no definite connexion with climatic conditions, and that, speaking generally, the sick, whether seriously or only trivially affected, have shown decreased powers of resistance.

I am, Sirs, yours faithfully,
June 10th, 1907. M.B.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

ALTHOUGH it is not yet the middle of June the summer session seems to be rapidly approaching its termination, for the examinations have commenced, and, indeed, the third medical examination, including materia medica and pathology, has already terminated, about three-fourths of the candidates having been successful in both subjects. The early commencement of the examinations might appear at first sight to be a distinct disadvantage to the students, inasmuch as it lessens the period of preparation as compared with other schools; nevertheless, as the system has worked well in the past there does not seem to be any obvious reason for changing, and it has the advantage of providing a long summer vacation which, to a certain extent, compensates for the short spring recess. The post-graduate lectures have been even more than usually successful this summer. Professor R. F. C. Leith lectured on the Present Position and Value of the Widal Reaction, Dr. C. J. Lewis dealt with the Bacteriological Diagnosis of Diphtheria, and Dr. J. Miller with Opsonins. Each subject was fully considered, all the latest facts being placed by the lecturers before their large audiences in a clear and concise manner, so that everyone could readily form his own opinion of the practical value of the processes dealt with. The last lecture, by Dr. John Robertson, on the Value of Preventive Methods against Infectious Diseases, was to have been given on June 13th, but it has been found necessary to postpone it for a week; it will be delivered therefore on Thursday, June 20th, at the usual time.

Birmingham Open Spaces and Playing Fields Society.

In a previous letter I drew attention to the attempt that this energetic society was making to secure the Black Patch as an open area in a crowded district and there is now no doubt that the attempt will be successful. It is probable also that advance that had been made in the subject within the last 16 years Dr. Jones pointed out that this had been greatly facilitated by the unlimited supply of electricity now available, owing to the energy of corporations and public companies. 12 years ago it had been quite a common occurrence for an electrical specialist to be asked to attend at a bladder examination with his cystoscope but so widespread had the knowledge of these previously little known appliances become that the rôle nowadays of the electrical specialist seemed to be to explore and to open up new fields and then to hand them over to the physician and surgeon. As regards diagnosis by means of electricity reference was made among other things to the diagnosis of obscure peripheral nerve lesions, cervical ribs, tubercle in the lungs, aneurysm of the aorta, and fracture of the base of the fifth metatarsal bone. In passing it was suggested that the present methods of electrical testing of nerves and muscles were antiquated and unsatisfactory and would have to be put on a better basis. In connexion with treatment Sabouraud's method of dealing with ringworm was described, also the treatment of rodent ulcer, tuberculous glands in the neck, and leucocythæmia by x rays. The treatment of cutaneous nævus by sparking with high-frequency sparks so as to produce a superficial burn was recommended, but skill was needed, otherwise it was impossible to prevent blistering and scar formation. Finally, reference was made to Leduc's method of ionic medication which has put kataphoresis on a new basis. The first essential of the treatment to be successful was to find out whether the substance to be introduced was an an-ion or a kat-ion. Of course, there were limitations to the applicability of this form of treatment. Ether and chloroform were not capable of introduction into the body in this way because they were insoluble in water without dissociation. Also some drugs owed their action to their concentration, and such drugs introduced diluted, as ions necessarily were, tended to lose their medicinal properties. This mode of treatment was being gradually developed and according to the lecturer it had great possibilities. In rodent ulcer good results had been obtained by using ions of zinc. For lupus ions of zinc, aniline, and fuchsin had been tried; copper and magnesium had also been made use of in the ionic method of treating warts and other superficial affections. A vote of thanks to the lecturer was carried on the proposition of the President of the Faculty of Physicians and Surgeons, Glasgow, seconded by Dr. Dawson F. D. Turner of Edinburgh.

The Tragedy at Montrose Asylum.

At the monthly meeting of the directors of the Montrose Asylum Dr. J. G. Havelock, physician-superintendent, submitted a statement regarding the tragedy which had occurred the previous week. He had assisted at a post-mortem examination on the man who was killed and it was found that the brain, the heart, and the kidneys were extensively diseased. The opinion was that the injuries received were insufficient to cause death in a healthy person. It was decided to institute an inquiry into the fatal assault and to ascertain if it might not be possible to make arrangements which would increase precautions during the night time. Once in two hours seemed to be rather long between the visits of attendants.

The Proposed Foresters' Convalescent Home for Scotland.

At the thirty-first annual conference of the Scottish Foresters' Federation which is being held in Aberdeen a report was submitted on the proposed establishment of a Foresters' convalescent home for Scotland. The report stated that the sum of £1989 was in hand for the purpose and members were urged to persevere in the work of raising funds. After a lengthy discussion the committee was given powers to add to its numbers and to look out for a suitable house and grounds for the purposes of a convalescent home, the committee to report to the next conference.

The New Water-supply for Aberdeen.

At the last monthly meeting of the Aberdeen town council it was resolved that Sir A. R. Binnie, M.Inst.C.E., and Mr. George R. Strachan, M.Inst.C.E., should, together with Dr. A. C. Houston, director of water examinations to the Metropolitan Water Board, be requested to report upon the subject of new or additional water-supply for the city.

Elgin Nursing Association.

At the half-yearly meeting of the above association it was reported that 246 cases had been dealt with during the past half year, as against 279 in the corresponding period of the previous year. The two nurses had paid 3681 visits. Reference was made to the donation of £500 which had been given to the association by Mrs. Woodhead, Hyde, a native of Elgin. The same lady has also presented a nursing home and some minor gifts. The association has a credit balance of £239.

June 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University Education in Ireland.

THIS matter, which is to a large extent medical, still occupies attention in Ireland. The *Irish Times* having copied a statement which had appeared in the *Times* to the effect that the Government had definitely abandoned Mr. Bryce's scheme as regards the University of Dublin, the *Freeman's Journal* on the same day published a long list of lay Roman Catholics who were in favour of what they thought might be the Government proposal—i.e., that one Roman Catholic college would be established in connexion with the University of Dublin, to which its students could apply for degrees. You have had a certain amount of correspondence on the subject in your columns but I have seen no reference to one matter which cannot be denied. The Roman Catholic bishops and clergy, as far as possible, close all Government and Poor-law appointments in Ireland against medical men holding the University of Dublin degrees. It is deplorable that the public health of the country should thus be endangered by its unfortunate religious dissensions.

Apothecaries' Hall of Ireland.

At a general meeting of the Members of the Apothecaries' Company, held at 40, Mary-street, Dublin, on June 7th, Mr. G. R. Seymour Stritch being in the chair, it was proposed by Dr. Montgomery, seconded by Dr. T. D. Finucane, and passed unanimously—

> That the best thanks of the Company are hereby tendered to Colonel Adye-Curran, M.D., F.R.C.S., for his untiring and successful efforts on behalf of this Hall in the General Medical Council.

The Irish Medical Association.

The annual general meeting of the Irish Medical Association was held this year, on June 5th, in the ballroom of the Northern Counties Hotel, Portrush, Mr. J. S. McArdle of Dublin, the President, being in the chair. From the report presented and adopted it appears that a sum of £297 17*s.* 2*d.* is still due to the law agent for law costs. The income received, with the balance in hand at the close of last year, was £901 18*s.* 6*d.*, and the expenditure was £838 17*s.* 11*d.*, leaving a balance of £63 0*s.* 7*d.* There is a balance to the guarantee fund of £60 16*s.* 3*d.* At the close of the year 126 members were in arrears for 1906, amounting to £130 14*s.* 6*d.* The President in his address, after thanking the members for re-electing him, spoke encouragingly of the work of the association, and thanked the Local Government Board for the manner in which it had received them at all times. He said that there were men in different districts in Ireland who belittled the association, although they belonged to it—a line which he denounced as cowardly, if nothing worse. He had nothing to say against the British Medical Association but why put it up, as it was being put up by members of that Association, as a rival to their own! Having impressed the lesson of unity the President said that every opinion which had been expressed by commissioners of late tended to demonstrate that there should be segregation of the profession in Ireland. Finally, he urged that they should in the future lend their strength entirely towards first securing proper scales of salaries all over the country, which could only be done by individual effort which he strongly recommended. Mr. J. S. McArdle was re-elected President of the association for the coming year; Dr. L. Kidd, Dr. W. MacSweeny, Dr. F. W. Kidd, and Dr. R. J. Kinkead, Vice-Presidents; Dr. J. Donnelly honorary secretary; and Dr. W. J. Thompson treasurer. In the evening the members dined together at the Northern Counties Hotel, the President being in the chair. On the next day there was an excursion to the Giants' Causeway.

Cerebro-spinal Meningitis in Belfast.

During the week ending June 1st 22 cases of cerebro-spinal fever were notified, the same number as in the previous week. Since May 30th 17 cases were notified, as against 20 of the finance committee in its recommendation to the city council to renew the grant.

Queen Alexandra Sanatorium, Davos: Meeting at the Town Hall.

A meeting in connexion with the Queen Alexandra Sanatorium, Davos, was held in the council chamber of the Liverpool town hall on June 10th. In the absence of the Lord Mayor the chair was taken by Sir Alfred Jones, K.C.M.G., and amongst those present were Lord Balfour of Burleigh, Sir James Barr, Sir Edward Russell, and many influential citizens. Sir James Barr moved a proposition to the effect that a fund for donations be opened in Liverpool in support of the scheme for providing an English sanatorium at Davos, which was carried. Lord Balfour addressed the meeting and described the perfect sanitary conditions of Davos and its advantages generally. The scheme aimed at aiding the lower middle-class and they offered medical treatment, with board, residence, and all the concomitants for one and a half guineas a week, which was almost as cheap as the treatment received at home. Lord Balfour mentioned that other towns had contributed liberally to the fund. Belfast had given £700 and he thought Liverpool could easily double that sum.

Proposed New Small-pox Hospital at Birkenhead.

The Birkenhead town council had before it at a meeting on June 5th the proposals of the health committee to extend the infectious diseases hospitals at Flaybrick-hill. The medical officer of the Local Government Board stated that the board was not in existing circumstances prepared to consider the application of the Birkenhead town council for sanction to borrow money for the erection of additional ward pavilions on the present site, but would be prepared to consider the application as regards the alterations and additions to the administrative block, the erection of a lodge and discharging block, and the reconstruction of the laundry block with the necessary machinery, upon certain undertakings being given by the town council. The inspector had further impressed upon the members of the sub-committee the desirability of the acquisition by the town council as early as possible of a separate site on which to erect a hospital for the treatment of small-pox patients. The committee recommended the purchase for £1069 of a piece of land, containing nearly nine and three-quarter acres, at Willaston as a site for a small-pox hospital in the event of the scheme not being opposed by the Wirral district council.

The Medical Officer of Health of Bootle.

Mr. T. W. N. Barlow, the medical officer of health of Bootle, will be called to the Bar this month, having successfully passed his examinations in English law for students of the Inns of Court.

June 11th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

A Milk-borne Epidemic of Scarlet Fever.

THE medical officer of health of Cardiff (Dr. E. Walford) has recently reported upon the circumstances attending an outbreak of scarlet fever during the second fortnight in May. Of the 37 cases of the disease notified during this period in a particular district 21 were supplied with milk from the same dealer and upon investigation it was found that the daughter of the farmer who supplied the milk was suffering from scarlet fever and that two other members of the family had had sore throats but no other well-defined symptoms. About 13 per cent. of the 150 houses supplied from this farm were infected. The supply of milk was promptly stopped and the outbreak was checked. Cardiff is well supplied with accommodation for the isolation of scarlet fever patients and the inhabitants make good use of the facilities provided. In the last few years as many as 75 per cent. of the cases of scarlet fever notified have been removed to the city isolation hospital. Expressed in percentages of the cases notified the mortality was 5 per cent. in the year 1891 before the hospital was opened, but in 1906 it was reduced to 0·4 per cent.

Gelligaer and Rhigos Isolation Hospital.

It has been decided by the Gelligaer and Rhigos district council to erect an isolation hospital at a cost of about £11,000. A site has been purchased for £260. The district adjoins Merthyr Tydvil and a portion is essentially rural in character, though there are many parts with urban features, and there are large collections of workmen's dwellings in which proper isolation of infectious disease is almost an impossibility.

Carmarthen Asylum.

The committee of visitors of the Joint Counties Asylum at Carmarthen has elected Dr. John Richards as medical superintendent of the asylum in succession to Dr. Edwin Goodall who was appointed last year superintendent of the asylum now approaching completion at Cardiff. Dr. Richards is at present senior assistant medical officer in the Leicestershire and Rutland Asylum and was formerly assistant medical officer in the Derby Borough Asylum. The Carmarthen Asylum has accommodation for 630 patients who are received from the three counties of Cardigan, Carmarthen, and Pembroke.

The Question of a County Medical Officer of Health for Monmouthshire.

In a recently issued report upon the sanitary administration of Ebbw Vale, a colliery district in Monmouthshire, Dr. Reginald A. Farrar, one of the medical inspectors of the Local Government Board, recommended that a medical officer of health should be appointed for Ebbw Vale and the adjoining districts who should devote his whole time to public health work. This recommendation has been discussed by delegates from the district councils concerned and they have arrived at the conclusion that a joint appointment for a combination of districts is not desirable, and in a communication addressed to the Local Government Board it has been pointed out by the delegates that the sanitary authorities are making strenuous efforts to improve the sanitation of their districts. It is very much to be regretted that this decision has been come to, for in increasing localities such as those in the Monmouthshire valleys, where the districts, though under different sanitary authorities, are actually close together, it is especially important that there should be uniformity of administration. Dr. Farrar's recommendation, if adopted, would most certainly make for efficiency and would be really economical. The county council has endeavoured to come to the assistance of the district councils by asking the Local Government Board to agree to the existing system of part-time medical officers of health at small salaries, provided a county medical officer is appointed "to supervise the work of the local officers." In this last expression there is displayed deplorable ignorance of the duties of a county medical officer who is the sanitary adviser of the county council and not the superior officer of the medical officers of health of urban and rural districts.

Schools and Pulmonary Tuberculosis.

At a meeting of the Devon education committee held on June 6th, under the presidency of Sir Thomas Acland, it was moved that no person should be employed in any school under the control of the committee who was suffering from pulmonary tuberculosis. The feeling of the committee was in favour of the proposal, but it was decided to refer the matter to a subcommittee in order that it might be carefully considered.

A Proposed Cornish Sanatorium for Consumptive Patients.

The Redruth board of guardians has been urging upon other boards of guardians in Cornwall the advisability of the Poor-law unions in the county uniting in the provision of a sanatorium for consumptive patients. The majority of the answers are not favourable to the proposition, the opinion being expressed that the guardians would derive all the benefits that they can wish by subscribing to the Didworthy Sanatorium on Dartmoor.

June 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

"The Really Useful in Electro-therapeutics."

AN interesting lecture on this subject was delivered on the evening of May 31st in the Western Infirmary, Glasgow, by Dr. H. Lewis Jones of St. Bartholomew's Hospital. There was a large and representative audience of medical men from Glasgow and the West of Scotland. In dealing with the emium will not be high, the sum of £1 yearly being fixed y the companies entitling the medical practitioner to a m of £4000 as a maximum in case of a claim for damages. part from this insurance, the Aerztekammer has secured r the local members of the profession personal insurance gainst accidents of all kinds, to include also attacks of fectious illness and syphilis if these diseases are contracted the course of professional duty. This will be a decided nprovement over the conditions in force hitherto, which ere so unfavourable for the practitioner that he was not able o obtain any compensation if he, for instance, in treating a atient suffering from typhoid fever or diphtheria, fell himelf a victim to one of these maladies. As a rule the comensation, which will be paid now to the insured practiioners, will amount to not less than £1 daily.

Molluscum Contagiosum.

At a recent meeting of the Dermatological Society Dr. Nobl showed a woman, aged 30 years, suffering from an nusual affection of the skin. On the left side of her chin here was a prominent, hard, flat tumour of the size of a hilling, round like a coin, imbedded in the skin, which at he site of attachment appeared pearl-grey. In the centre here was a scab, somewhat depressed, but fixed to the umour. The tumour appeared for the first time eight weeks ago and grew quickly in spite of the application of several kinds of ointment. The differential diagnosis between a primary syphilitic sore, an epithelioma, or a fibrous nævus and molluscum contagiosum, as the disease really was, depended on the absence of reaction in the neighbourhood and the extreme hardness of the mass. The rapidity of growth allowed the inference that the morbific agent was of exceptional virulence. In such cases transplantation of the molluscum was possible and has been successfully tried by Dr. Nobl himself. The diagnosis of the disease during the pre-histological epoch was often very difficult, as inveterate acne might simulate it very closely. The only treatment for molluscum was radical excision, which was a very simple procedure.

An Interesting Combination of Pathological Conditions.

In a subject dissected by Dr. Sternberg, the pathologist to the Brünner General Hospital, there was found associated in one patient a series of conditions of which each one was considered to be a rarity. First of all, there was an aneurysm of the descending thoracic aorta which had completely eroded two ribs on the left side and the left half of the vertebral column between the third and the seventh vertebræ, so that a soft tumour, palpable under the skin of the back, resulted. This tumour had been several times diagnosed as a cold abscess and had once narrowly escaped surgical treatment. The cause of death, however, had been a dissecting aneurysm of the ascending part of the aorta, which had permitted blood to ooze between the layers of the aortic wall into the pericardium, thus compressing the heart gradually. The aorta in this part showed signs of another rupture of the sac, which undoubtedly had taken place a long time ago and had healed up by scar tissue. After the scars had formed they became thinned until at last the dissecting aneurysm was established. Chronic aortitis was present throughout the whole length of the vessel, with many patches of calcified tissue. On the left foot the characteristic sore of perforating ulcer of the foot was found and tabetic changes of the spinal medulla were distinctly marked. Clinical manifestations during the life of the man were in accordance with the conditions found at the necropsy. Syphilitic stigmata were present and notwithstanding the denials of the patient syphilis was undoubtedly the basis of all these changes.

Report of the Vienna Polyclinic.

The thirty-fifth yearly report of the institution known as the Polyclinic in Vienna has just been published and shows that a large amount of work has been done during the twelve months in question. In 1872 the number of out-patients was 11,952, last year it went up to 69,527, and during the 35 years 1,500,000 new out-patients were treated. In 1887, when the in-patient department was founded, the number of in-patients was 80. Last year the institution had 150 beds and 2247 in-patients were admitted, 671 of them being children under 14 years. These patients included 119 cases of diphtheria admitted to the isolation ward; 112 of them received injections of serum but the remaining seven arrived medical aid. The mortality of diphtheria treated by serum injections has fallen to 3·3 per cent. of all cases injected. 1070 major operations were performed with a mortality of 4 per cent. 115 mastoid operations were performed in the otological department, with one death (a case of tuberculous otitis with meningitic complications). A new laboratory for x ray work has been provided. The institution is one of the very few in this city the income of which is derived from charitable contributions or bequests. For the first time since its erection the expenditure exceeds the income, so that a deficit of about £3000 remains. The polyclinic comprises, as its name states, departments for all branches of medicine and the heads of departments are either extraordinary professors or *privat-docenten*. It is a rule that only first-class men are appointed to these posts, as the institute is in close connexion with the university and the lectures delivered in it are well attended by graduates from all countries. It stands even higher in the public estimation than the general hospital, for with the exception of the heads of departments the staff of the polyclinic are mostly engaged in general practice and the hours of consultation at the polyclinic are more convenient for the public than at the general hospital.

June 10th.

CONSTANTINOPLE.

(From our own Correspondent.)

The Thermal Springs of Turkey.

The authorities last year decided to gather all the necessary data and information concerning the thermal springs of the Ottoman Empire, with the view of publishing their therapeutic properties, composition, mode of access, and the like. The question was also considered of opening comfortable hotels at the watering-places, of constructing new roads of communication, and of rendering, in other ways, the thermal springs attractive to the general public. This rather extensive scheme is, however, still unrealised, although plans for putting it into operation were published only recently. As usual in Turkey want of funds is the stumbling-block. Yet the accomplishment of the above plans could, in a comparatively short time, be a fruitful source of revenue to the Ottoman State treasury, the more so as many of the Turkish thermal springs, especially those scattered throughout Asia Minor, are either near the main railway lines or situated in proximity to the sea. The vilayet of Hudavendighiar, a neighbouring province to the metropolis, is the most remarkable and the best adapted for the exploitation of its hot springs. The town of Brusa, for instance, the ancient capital of the Ottoman Empire, has long been famous for its hot iron and sulphur springs which have a temperature ranging from 112° to 178° F. Every year in the spring months it attracts numerous people and many tourists from Europe. Another much frequented thermal place is Courz-les-Bains-Yalvoa. Patients suffering from rheumatism, from diseases of the bladder, from some forms of paralysis, and from skin diseases are said greatly to be benefited by these baths. They are under skilful medical supervision and of recent years several new establishments have been added and the old Roman baths have been improved. Yalvoa is also visited by people suffering from different nervous complaints. It is within easy reach of Constantinople, commands a magnificent view over the Sea of Marmora, and has pure, exhilarating air. It is a real country place, with the advantages of a bathing resort equipped more or less in a modern style.

Mortality Returns.

Last week 238 people died in Constantinople, of whom one died from scarlet fever, two from small-pox, five from enteric fever, 52 from tuberculosis, and three from cerebro-spinal meningitis.

June 7th.

Cardiff Infirmary.—Up to the present £9267 have been received towards the £30,000 required by the committee of the Cardiff Infirmary for the purpose of erecting a new wing and making other required additions to the institution.

during the previous week, bringing the total up to 482; and during the week ending June 1st 14 deaths were reported, a decrease of six, as compared with the previous week. The total number of deaths since the beginning of the outbreak was 350. The cases are now milder and it is hoped by the medical officer of health that the worst of the epidemic is perhaps over. Of the 81 patients in Purdysburn Fever Hospital on June 6th 41 were cases of cerebro-spinal meningitis.

Royal Sanitary Institute Conference.

A conference on sanitation and public health has been arranged by the Royal Sanitary Institute to be held in Trinity College, Dublin, from June 25th to 29th next.

June 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Influence of the Emotions in Hæmoptysis of Tuberculous Origin.

AT the Society of Internes of the Paris Hospitals on May 23rd M. Boisseau reported the case of a young girl suffering from tuberculosis who had at the beginning of the disease two "vicarious hæmoptyses" (*supplémentaires de règles*) and five hæmoptyses following emotional disturbances; they always followed immediately on the entrance into the patient's room of a certain friend of the family with whom she was violently in love and whose visits invariably caused her great agitation. During the attacks of hæmoptysis she had some congestive râles and a slight evening rise of temperature, but these symptoms only lasted a few days. The attacks exactly corresponded with those described as hysterical hæmoptyses. They were, however, undoubtedly of tuberculous origin, for later Koch's bacillus was found in the sputum and the patient died from acute double tuberculous broncho-pneumonia. Although she was a very emotional girl she showed no other symptom of hysteria. This case tends to prove that so-called hysterical hæmoptyses have no really distinctive features and that they cannot be diagnosed from some tuberculous hæmoptyses; that only the combined presence of hysterical stigmata and absence of auscultatory signs of tuberculosis can justify the diagnosis of hysteria. And so on one hand the latency and frequent early arrest of tuberculosis, and on the other the association of this disease with a neurosis, give good grounds for thinking that most of the cases described as "hysterical hæmoptyses" are really of tuberculous origin occurring in hysterical subjects in whom the disease had been arrested.

Optical Treatment of Strabismus.

At the Academy of Medicine on May 28th M. de Lapersonne reviewed the optical treatment of strabismus. He does not advise operative treatment before ten or 12 years of age; the use of correcting glasses, the use of atropine drops, and the intermittent wearing of a bandage on the sound eye are the essential points in the treatment. Later recourse may be had to operative procedures, but it is necessary to supplement them by optical exercises with the aid of that very ingenious instrument called the diploscope invented by Dr. Remy. With the intelligent employment of the diploscope the cure of strabismus can be guaranteed and often in quite a few sittings.

Cardio-vascular Affections in Hereditary Syphilis.

At the same meeting of the Academy of Medicine M. Landouzy and M. Loederich gave an interesting account of some cardio-vascular lesions connected with hereditary syphilis. The case in question was that of a child, born at full term but who died within five weeks from broncho-pneumonia. A post-mortem examination showed that there were serious cardiac malformations, but these, despite their serious nature, incomplete interauricular septum, imperfect development of the aorta, and hypertrophy of the right ventricle, had given no signs during life, either physical or functional. The kidneys and the suprarenal bodies also showed the lesions associated with hereditary syphilis. There was no reason to suppose that they were due to either alcoholism or tuberculosis in the parents.

Vaccination in Algeria.

Vaccination has been made compulsory in Algeria during the first year of life and revaccination in the course of the eleventh and twenty-first years. Vaccination is also obligatory upon any person wishing to reside in the country. The vaccination organisation for each province is under the control of the prefect who nominates the medical men, the midwives, and the other officials who have to do with the vaccination service. Those who disobey the regulations render themselves liable to penalty.

Tramcar Tickets and Infectious Diseases.

Dr. Busquet, a medical man of Bordeaux, has recently been making some inquiries into the question as to whether infection could be conveyed by the tickets handed to passengers by tramcar conductors. He took great care to avoid any contamination of the tickets after he received them. Having provided himself with sundry double envelopes made of "bank" paper (*papier Joseph*) he exposed them for one hour to a heat of 180° C. Then he started on a round of journeys by the different tramways in Bordeaux. When he was given a ticket he tore off the corner by which he had held it and dropped the remainder into one of his sterilised envelopes. In all he received ten tickets from five conductors, all of which were defiled with saliva. Cultures were then made from the tickets, which showed the presence of numerous germs such as streptococci, staphylococci, pneumococci, and the pseudo-bacillus of Loeffler. White mice inoculated with some of the culture bouillon were gravely affected, and out of ten so treated eight died. Five white rats which were inoculated all died.

Monument to Théophile Roussel.

On June 5th the monument erected to the memory of Théophile Roussel was unveiled; the ceremony was performed by M. Fallières, President of the Republic. As is well known, Théophile Roussel devoted his whole life to improving the lot of foundling children (*assistés*) and protecting their interests. Speeches were made by the Minister of Labour, M. Viviani, who drew a picture of the beauty of Roussel's life; by the Prefect of the Seine, M. de Selves; and others. The proceedings were brought to a close by the distribution of prizes to the foundlings.

June 10th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Resignation of Professor Chrobak.

AT the end of the current summer term Professor Chrobak, the famous gynæcologist, will resign his post as ordinary professor and director of the gynæcological clinic in the University of Vienna. In his case the age limit of 70 years would not take effect for three years yet, but the state of his health has compelled him to relinquish the post occupied by him for many years, and his decision has been received with the greatest sorrow by his numerous pupils and patients. Professor Chrobak is famous for his correct and exact diagnoses, his conservative methods of treatment, and his great success as an operator. As a teacher he won the esteem and attachment of all his students. His successor will presumably be Professor von Rosthorn, at present director of the gynæcological clinic in the University of Heidelberg. The new professor will not have to teach in the present Vienna clinic, which is too small for the requirements of a modern surgeon, but will enjoy the advantage of being the first clinical teacher to take over the new clinic at present in course of erection, where an up-to-date institution awaits him and where every requisite for modern scientific research will be at his disposal.

Medical Defence and the Insurance of Medical Men against Accident or Injury.

The serious risks which a practitioner, especially a surgeon, incurs when his treatment does not prove satisfactory to the patient have led the Aerztekammer (Medical Council) to take a very praiseworthy step for the protection of the members of the profession. A committee has been appointed by the Aerztekammer for the purpose of entering into negotiations with several large insurance companies to obtain favourable rates for the medical men. The companies have consented to grant insurances against charges of malpractice and will provide counsel for the defence in all cases of this kind besides fixing an amount sufficient to cover all claims in each case; full particulars must in every instance be notified to the Aerztekammer, which will instruct counsel. The of £700 per annum from the University chest. This may or may not be augmented hereafter by a Fellowship in a College.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION OF ENGLAND AND WALES.—The annual general meeting of this association will be held at the Trocadéro, Piccadilly-circus, London, W., on Thursday, June 27th, at 6.30 P.M. At 7.30 the members and their friends will dine together, and as the dinner this year is to be of an informal nature evening dress will not be necessary. There will be a musical entertainment, and the honorary secretary will be glad to hear from any member willing to assist, either with vocal or instrumental music. The price of the dinner will be 7*s.* 6*d.*, exclusive of wine. Members may introduce friends and all Poor-law medical officers are cordially invited. Those desiring to be present are requested to communicate with the honorary secretary, Dr. M. Greenwood, at 144, Stoke Newington, London, N.

THE CORONERS' SOCIETY OF ENGLAND AND WALES.—This society held its annual meeting on June 11th, which was followed by a banquet in the evening at the Holborn Restaurant, London, W.C., under the chairmanship of Mr. Charles L. Rothera, coroner for the city of Nottingham, the President of the society. The company was very hospitably entertained and an excellent programme of vocal music was rendered between the speeches by the Princes' Quartette. After the loyal toasts had been given from the chair Mr. I. Bradley (coroner for Birmingham) proposed "Imperial and Local Government," to which Mr. J. H. Yoxall, M.P., responded. Mr. Alex. Macmorran, K.C., next gave the toast of "The Coroners' Society," and pointed out the great help which it afforded to its members in advising them on the many matters of difficulty arising in connexion with their ancient office. He showed that there was a real need for this assistance, as the office was not statutory, but that its powers could only be defined from the Common Law existing before Coke's day. The decisions embodied in the annual reports of the society were forming a body of information that could not be found in the text-books and were of the utmost value in administering coroners' law. Of late years the public respect for the coroner's office had increased with its responsibilities largely through the society's influence. In reply, the chairman also testified to the extreme value of the society's reports and alluded to the increased interest shown in its discussions by its members. It had frequently to defend its members from the attempts of county councils to encroach on their functions. The society might and ought to exert a powerful influence on legislation in such matters as the registration of deaths and the control of midwives. Dr. F. J. Waldo, coroner for the City of London, proposed "The Guests," for whom his honour Judge Bentoul and Mr. A. J. Davies, Permanent Secretary to the Welsh Department of the Board of Education, replied. Mr. Henry White proposed "The Past President and Present Officers," expressing the great debt of gratitude that the society owed to its very energetic secretary Mr. W. Schröder. Mr. G. P. Wyatt, coroner for South London, and Mr. Schröder, deputy coroner for Central London, replied. The latter gentleman said that reform on many subjects—e.g., death certification—was essential; the Lord Chancellor was carefully considering the proposals put forward by the London County Council to amend the law governing coroners, which he hoped would receive vigorous support; the suggestions were not new, as a medical coroner so far back as 1862 had employed special pathologists to perform necropsies. Mr. Schröder expressed his thanks to Mr. Benson for assisting him in preparing the annual report of the society.

THE JUBILEE INSTITUTE FOR NURSES: QUEEN ALEXANDRA'S COMMITTEE.—Her Majesty the Queen, who takes a deep personal interest in the work of her nurses, has nominated Adeline Duchess of Bedford in succession to the late Countess Cadogan as president of her committee charged with the financial welfare of Queen Victoria's Jubilee Institute for Nurses. Membership of Queen Alexandra's committee in 1906 was limited to 25 ladies who undertook to be responsible for raising £100 each on behalf of the institute. It was, however, felt too much to expect them to repeat such a task annually and a decision was arrived at and sanctioned by the Queen enlarging the committee to one comprising 200 members who would collect £10 each yearly whereby £2000 would be guaranteed annually. This larger committee was in course of formation when progress was stayed by the death of Lady Cadogan. The recent nomination will, it is hoped, shortly lead to the completion of the list of membership which in due course will be submitted to Her Majesty for approval. The work of the Queen's nurses who tend the sick poor in their own homes without distinction of creed becomes increasingly known every year. Support is always willingly given to district nursing associations when the nurses are daily seen in the active pursuit of their duties. Before a district can secure the skilled services of a Queen's nurse she has already cost the Central Institute from £30 to £40 for training in district or midwifery work. In addition, a large annual expenditure is necessary in the periodical inspection of each nurse and her work, which is regarded by the local committees employing Queen's nurses as a most valuable feature in the institute's work. The conduct of the institute in Scotland is under the control of a special Scottish council, aided by a large annual grant from the Central Council, which provides entirely for the administration of the work in England, Wales, and Ireland. At the beginning of the present year 1450 nurses were on the Queen's roll. These, with Queen's probationers, village nurses, and midwives bring the total to 2190 nurses who come under the supervision of the institute. The administrative work also involves the calling of important annual conferences on matters concerning district nursing, at which there are often from 200 to 300 persons present representing district nursing associations from all parts of the country. A large expenditure is necessary to maintain the work, and when it is realised that annually a deficiency of £2000 has to be met in keeping pace with the growth of the work financial support it is hoped will be given willingly. The honorary treasurer of Queen Alexandra's Committee, Mr. Harold Boulton, M.V.O., and the secretary, Mr. Reginald Garratt, will gladly reply to any inquiry as to the work on applications being addressed to them at the offices of the institute, 120, Victoria-street, London, S.W.

COMPLIMENTARY DINNER TO PRINCIPAL DONALD MACALISTER.—On June 4th a complimentary dinner was given to Dr. Donald MacAlister in the Combination Room of St. John's College, Cambridge, by the resident medical graduates of the University. The Regius Professor of Physic occupied the chair and among those present were: Sir Hector Cameron, Sir Robert Ball, the President of Queen's College, Cambridge; the following professors: J. N. Langley, J. B. Bradbury, J. J. Thomson, Howard Marsh, G. Sims Woodhead, G. H. F. Nuttall, and Brodie; Dr. W. H. Gaskell, Mr. Adam Sedgwick, Mr. A. E. Shipley, Mr. F. G. Hopkins, Dr. L. Humphry, Dr. L. E. Shore, and others. Professor Allbutt, in proposing the guest of the evening, pointed out that the University was losing a great pioneer whom it could ill spare, and described how the Scotch usually took the cream off the English bowl, though in securing Dr. MacAlister as a Scottish principal they were getting some of their own back. After paying a high compliment to the poetry, romance, and literature of Scotland, he went on to dwell on the celerity of business, the financial progress, and the general efficiency of the General Medical Council since Dr. MacAlister had become the President of that body, adding that he was glad to think that the principal of the University of Glasgow would still continue to represent Cambridge on that Council, and concluding with reference to Lord Kelvin and the late Sir Richard Jebb, illustrious Cambridge Glaswegians. Dr. MacAlister, in reply, said that he had spent 26 years in Cambridge in the medical school and University. He remembered how he had been hampered by being Senior Wrangler and how he had had great difficulty in living down the part by ignoring the claims of mathematicians and cultivating the realms of science and medicine. In 1877, when he joined Cambridge as a medical student, there were only 40 "medicals" in the year, and only 100 students of medicine in the whole University. Last October 122 medical undergraduates matriculated and the total was 420. The number had increased on account of the modern equipment, the high standard required, and the enthusiasm and stimulation of the teachers. He touched lightly on his work on the General Medical Council and as chairman of the special board for medicine in Cambridge. His only difficulty when he had 24 hours in which to decide whether or not he should accept the position of principal of the University of Glasgow was the resignation of the chair of the General Medical Council, which he thought that his acceptance of the post offered

Obituary.

MAXWELL TYLDEN MASTERS, M.D. ST. AND., F.R.S.

THE death is announced of Dr. Maxwell Masters as occurring at Ealing on May 30th. Born at Canterbury on April 15th, 1833, he was the youngest son of parents of unusual ability who were much in advance of their time. Having entered as a medical student at King's College, London, he in due course passed the examinations of the Royal College of Surgeons of England and of the Society of Apothecaries of London and went to Oxford as subcurator of the Fielding Herbarium under Dr. Daubeny. In 1856 he commenced general practice at Peckham in partnership with Dr. Stokoe; this he relinquished after a few years to devote his whole time to scientific botany. In 1866 he became part editor of the *Gardeners' Chronicle* and sole editor from 1882 till the time of his death, thus having been connected with that journal for 41 years. Here he found work thoroughly congenial to his taste and was the animating personality in its fortunes, gathering around him as contributors all the leading men of science and horticulture in all countries. A man of wide culture and attractive personality, as became the successor of Dr. Lindley, one of his earliest works of importance was a volume on "Vegetable Teratology" issued in 1869 by the Ray Society; in 1870 he published a revised edition of Henfrey's "Elementary Botany." His scientific monographs are too numerous to mention, for he was untiring in his devotion to the science of his choice. He was lecturer in botany at St. George's Hospital from 1865 to 1868 and for several years acted as examiner in botany in the University of London and for the Society of Apothecaries. He was a Fellow of the Royal and Linnæan Societies, was a Corresponding Member of the Institute of France, and an Officer of the Order of Leopold, and was in one way or another associated with the leading horticultural and botanical societies in Europe and America.

DAVID MACBETH MOIR, M.D. EDIN.,

MAJOR, INDIAN MEDICAL SERVICE.

Major David Macbeth Moir, who died in Calcutta on June 7th, represented the third generation of a medical family. His grandfather, Dr. David Macbeth Moir, practised in Musselburgh where a statue has been erected to his memory. He acquired a great reputation by his literary work, much of which appeared under the author's pseudonym of "Delta." Major Moir was born in India in 1860, being the eldest of the family of the late Dr. Moir, who, after returning to Scotland, practised in St. Andrews. He studied medicine at the University of Edinburgh, where he graduated as M.B. in 1885. After becoming qualified he was made demonstrator of anatomy in the University of Edinburgh and held residential appointments in the Royal Infirmary, Chalmers' Hospital, Royal Hospital for Sick Children, and Royal Maternity Hospital, Edinburgh. A description of a case of avulsion of the fingers which appeared in THE LANCET of March 3rd, 1888, was written by him while at Chalmers' Hospital. In 1888 he went to India as surgeon-captain in the Indian Medical Service, having gained during his course of instruction at Netley Hospital a gold and a bronze medal and having passed second on the list of candidates for the army. In India he served with the Chin-Lushai expeditionary force in 1889–90 and was awarded a medal with clasp. He afterwards held various civil appointments, including one at the Presidency General Hospital, Calcutta, where he acted for the medical superintendent when the latter was on furlough. Reports of surgical operations performed by him in this hospital appeared in THE LANCET of Jan. 9th and April 24th, 1897. In 1898 he also published in our columns two articles giving a summary of 193 cases of gunshot wounds treated by him at Rawal Pindi. In 1899 he took home leave for a year, during which he graduated as M.D. at his University, receiving high commendation for his thesis. In March, 1900, he was promoted to the rank of major. After his return to India he continued to hold civil appointments and was eventually made professor of surgical and descriptive anatomy in the Medical College, Calcutta, and became *ex-officio* surgeon to the hospital of the college. He therefore had every prospect of a most promising career, which has been abruptly terminated by his sudden and untimely death.

Medical News.

UNIVERSITY OF CAMBRIDGE.—By the death of Professor Alfred Newton, F.R.S., Professor of Zoology and Comparative Anatomy since 1866, the University loses an accomplished naturalist who in the domain of ornithology was acknowledged to be of the highest authority.—Professor G. H. F. Nuttall announces that the Secretary of State for the Colonies is prepared to make a grant of £100 a year for two years for the purpose of establishing a research studentship in medical entomology in the University. Applications are to be sent to Professor Nuttall by June 17th.—A Balfour studentship in Animal Morphology, of the value of £200 a year for three years, will be vacant at Michaelmas. Applications are to be sent to the Registrary, Cambridge, by Oct. 1st.—Dr. G. S. Graham-Smith, Professor Nuttall, and Professor G. Sims Woodhead are appointed delegates to the International Congress of Hygiene and Demography to be held in Berlin in September next.—Dr. L. Humphry has been nominated as assessor to the Regius Professor of Physic for the ensuing academical year.—At a Congregation on June 6th the following degrees were conferred:—

M.D.—W. E. Moore Ede and G. R. Rickett, King's; J. Wharton, St. John's; E. H. Harrisson and B. Hudson, Clare; C. R. Howard, Pembroke; and S. L. O. Young, Christ's.

M.B. and B.C.—H. J. Clarke and G. G. Packe, Trinity; and L. Nicholls, Downing.

M.B.—W. H. R. Sutton, Downing.

B.C.—A. T. Densham, St. John's; and G. F. Greenwood, Sidney Sussex.

THE BELGRAVE HOSPITAL FOR CHILDREN.—A summer fair and Spanish market was opened at Prince's Skating Rink, Knightsbridge, on June 10th in aid of the Belgrave Hospital for Children, Clapham-road, London, S.W.

LITERARY INTELLIGENCE.—Dr. J. S. Milne has completed a long monograph on "Surgical Instruments in Greek and Roman Times," which will be issued from the Oxford University Press within a few days. The volume embodies investigations extending over several years and is fully illustrated. The author points out that many interesting operations described in detail in ancient authors are rendered obscure or quite unintelligible from lack of knowledge of the instruments employed, while no systematic attempt to reconstruct the different instruments used by the ancients has hitherto been made, this department of archæology having received scant attention.

UNIVERSITY OF OXFORD.—The following have been appointed public examiners in the branches of natural science indicated: W. N. Stocker, M.A., Fellow of Brasenose College, in Physics; N. V. Sedgwick, M.A., Fellow of Lincoln College, in Chemistry; W. Ramsden, D.M., Fellow of Pembroke College, in Physiology; and A. Dendy, D.Sc. Lond., in Zoology.—The Earl of Rosebery, Hon. D.C.L., Hon. Student of Christ Church, a Rhodes Trustee, unveiled a tablet to commemorate the foundation of the Rhodes scholarships, *in the Examination* Schools on June 12th.—The Herbert Spencer lecture for 1907 was delivered on June 5th in the Sheldonian Theatre by Francis Galton, Hon. D.C.L., M.A., Hon. Sc.D. Cambridge, F.R.S., Hon. Fellow of Trinity College, Cambridge, the title of the lecture being "Probability the Foundation of Eugenics."—The Margaret Ogilvie Reader in Ophthalmology announces his fourth annual summer course in ophthalmology, to be held from July 15th to 27th. The course (*fee £5 5s.*), which is not confined to members of the University, will consist of lectures and practical instruction and demonstrations by the Reader, assisted by a number of distinguished English and foreign ophthalmologists and others.—The electors give notice that they intend, if possible, to proceed to the election of a professor of pathology early in the month of July. Candidates are requested to send their applications to the Registrar of the University on or before *July 1st.* No testimonials are to be submitted, but candidates should send in, with their names, ten copies of a statement of their qualifications, accompanied by references or any other evidence which they may desire to offer. The professor of pathology is bound by statute to lecture and to give instruction in pathology. He also has charge of the pathological laboratory and of the pathological collections belonging to the University. He is not allowed to engage in private medical or surgical practice. The University guarantees an income of London inebriates to reformatories in suitable cases, so that the Inebriates Act might not be made largely inoperative so far as London was concerned.—Mr. Gladstone replied (by written answer): My attention has been drawn to the decision of the London County Council to discontinue its present provision for the reception of all classes of female inebriates and to restrict its work to a few selected cases eligible for Farmfield, and there is no doubt that if this policy is maintained the London magistrates will be deprived of the opportunity to commit female inebriates to reformatories save as regards a few isolated cases. I am about to communicate with the Council upon this important matter.

THURSDAY, JUNE 6TH.

Vivisection Licences.

Mr. Smeaton asked the Secretary of State for the Home Department whether, in addition to the two inspectors, Dr. Thane and Sir James Russell, and the Association for Research mentioned in the appendix of the first report of the Royal Commission now sitting, he had any other expert advisers in the matter of vivisection licences, and, if so, whether, in accordance with the recommendations of the Royal Commission of 1876 to the effect that the names of these advisers should be known to the public, he would inform the House of the names of these other expert advisers. Mr. Smeaton further asked the Home Secretary whether, if his expert advisers in the matter of vivisection licences consist solely of the Association for Research and the two inspectors, he would, in view of the opinions and advice tendered by the Royal Commission of 1876, add to his advisers some independent persons whose interests were not bound up with those of the vivisectors.—Mr. Gladstone said, in reply: As I have already informed my honourable friend the usual procedure in applications made to me for licences to perform experiments on living animals is set out in the appendix to the first report of the Royal Commission on Vivisection. Occasionally, where questions of great importance have arisen upon which it was advisable to obtain the opinion of the highest authorities, the Royal Colleges of Physicians and Surgeons and the Pharmaceutical Society have been consulted. I do not propose to make any change in the existing practice pending the report of the Royal Commission now sitting. The Commission of 1876 said that the advisers of the Secretary of State ought to be persons "of competent knowledge and experience" and the inspectors satisfy this description. I may add that no licence or certificate is granted without the recommendation of the eminent authorities mentioned in section 11 of the Act of 1876.

The Condition of Belfast Factories.

In answer to Mr. Devlin, who asked whether the Home Secretary was aware that many of the girls in the Belfast textile factories complained of the bad air in them and that the death-rate from consumption amongst the workers was high, Mr. Gladstone said that the conditions in the flax and linen factories in Belfast were recently made the subject of a special inquiry and new regulations had been issued which should lead to a considerable improvement in the ventilation and generally in the conditions under which work was carried out.

Medical Posts at His Majesty's Embassies.

Sir William Collins asked the Secretary of State for Foreign Affairs whether he would state to how many of His Majesty's embassies and consulates medical officers or advisers were attached, what were the medical and surgical qualifications required of candidates for such posts, and what were the salaries and conditions of service attached to each of them.—Sir Edward Grey furnished the following written answer: The salaries and allowances provided for medical officers are given in the estimates for diplomatists and consular services under the names of the various posts. The officers are duly qualified practitioners and those who receive allowances are usually selected on the spot. The following are the principal posts: Constantinople, £700; Peking, £650 to £703; Alexandria, £500; Tokio, £350; Tehran, £600; Bangkok, £250, and Zanzibar, £400. Quarters are provided at Peking and Tehran. Officers who take private practice are not pensionable.

The Plague in India.

Several allusions to the plague in India were made in the course of the debate on the Indian Budget.

Mr. Morley (the Secretary of State for India) in the course of his annual Budget statement, said that this was a prosperity Budget. He had, however, to admit that a black shadow fell across the prospect, for the plague figures were appalling. But let them not get unreasonably excited about the appalling figures. If they had reckoned the plague figures last September they might have hoped that this terrible scourge was on the wane. From 92,000 deaths in the year 1900 the figures went up to 1,100,000 in 1904, and they exceeded 1,000,000 in 1905. In 1906 a gleam of hope arose and the mortality sank to something under 500,000. The combined efforts of the Government and of the people produced that reduction, but, alas, since January, 1907, the plague had again flared up in districts which had been filled with its terror for a decade. For the first four months of this year the deaths were 642,000, and exceeded the record for the same period in any past year. Honourable members must remember that they had to cover a very vast area, and he did not know if these figures would appal them if they took the area of the whole of Europe. It was in 1896 that the plague first appeared in India, and up to April, 1907, the total figure of those human beings who had died from it was 5,250,000. But dealing with a population of 300,000,000 this great mortality, although enormous, was not at all comparable with the Black Death and other scourges which spread over Europe in earlier times in proportion to the population. The plague mortality, which was higher this year than in 1904, only represented a death rate of about 3 per 1000. It was local and particularly centred in the Punjab, the United Provinces, and Bombay. No one, he cared not to what school of Indian thought he belonged, could deny that measures for the extermination and mitigation of this disease had occupied the most serious, constant, unflagging, zealous, and energetic attention of the Government of India. But the difficulties which they encountered were enormous. It was possible that it might be said that afternoon by some honourable Members that the Government was not enforcing with sufficient zeal proper sanitary rules, but he was certain that other honourable Members would point out that the great difficulty in the way of sanitary rules being observed arose from the reluctance of the population to practise them. They were naturally suspicious and when all these new rules were forced upon them they naturally resented and resisted them. He would not detain the House with the details of all the proceedings they were taking. They had instituted long scientific inquiries with the aid of the Royal Society and the Lister Institute. Then they had very intelligent officers, who had done all they could to trace the roots of this [illegible] if they could, any means to prevent it. It was [illegible] appeared to be no immunity from this [illegible] there was an almost entire immunity [illegible] difficult to understand this immunity. The right honourable gentleman then proceeded to deal with other topics.

Dr. Rutherford, who took part in the subsequent debate, said that the plague was one of the chief causes of the unrest in India. It was a preventable disease. It had been brought under control in most countries and only in India had it had such awful effects. The Government had not, in his opinion, taken sufficient measures to cope with this terrible scourge. It had been advised by the highest medical authorities, with a knowledge of India, that it should engage a sanitary army composed entirely of Indians, so that there might be no degradation of Indian homes by the entrance of foreigners, to see that the sanitary requirements were carried out. In his opinion the Government of India could not better spend the surplus at its disposal than in providing such a sanitary army.

Mr. Hobhouse (the Under Secretary for India), speaking towards the end of the debate, said that no one could fail to sympathise with the people of India in the horrible infliction of plague which had fallen upon them. But that was not the hand of man. It was the hand of God.

Sir H. Cotton: Do not blame God for it.

Mr. Hobhouse said that no man was more moved by the sufferings of the people of India than was the Secretary of State. Let the House consider what the Indian Government had done to mitigate this misfortune. The subject had been engaging its attention. It had made careful inquiries and taken such measures as were within its power and as the state of the people would permit. The Government of India could not press the people too much, because this might rouse more dislike for the measures of relief than was likely to promote their success. The success of the measures depended upon the coöperation of the people themselves. It was freely admitted that in some ways the executive which dealt with the plague wanted strengthening. They were prepared to supply native medical men acquainted with the habits and customs of the people and sufficiently trained in sanitary science to cope with this great evil and also to supply native servants well acquainted with the measures to be taken for the relief of plague. One point greatly excited the interest of the people of India. They asked how it was that natives died in millions and Europeans by single individuals. It was easy to understand how in the minds of an ignorant and easily excited population suspicion might be aroused by the disparity in the numbers who died. Scientific investigations had shown that the plague was largely disseminated by the agency of rats and of the fleas which infested the rats, and it was a fact that rats were mostly found in native houses. A further cause of contamination was germs in the soil, and the natives, who walked barefooted, took up the germs from the earth, while Europeans were protected by their shoes. Laboratories were being widely established to meet all demands for inquiry and all possible means which human ingenuity could suggest and science could devise were being taken by the Government of India to cope with the evil.

FRIDAY, JUNE 7TH.

Tramway Tickets and Disease.

Mr. Summerbell asked the Secretary of State for the Home Department whether his attention had been called to an analysis of tramway tickets carried out by Dr. Busquet of Bordeaux, and the statement made in relation thereto that four out of five tramway tickets taken at random in Paris might transmit dangerous diseases; and, if so, would he state whether he was prepared to have an analysis of tramway tickets in London.—Mr. Gladstone (in a written answer) replied: My attention has not been called to this matter, and, as at present advised, I do not think there is any need to take such steps as the honourable Member suggests.

MONDAY, JUNE 10TH.

Insanitary Schools in Ross-shire.

Mr. Weir asked the Secretary for Scotland whether he would state in what way he proposed to deal with the sanitary defects in the public schools on the western mainland of Ross-shire and the Island of Lewis, as disclosed in the statement made by the medical officer of health of the county in his last report, to the effect that there was still much to do in the case of schools on the West Coast and the Lews, particularly with regard to the want of a due supply of pure water and the filthy condition of the cloakrooms and usual conveniences.—Mr. Sinclair replied: On the general question raised by my honourable friend I may refer him to the Local Government Board report for 1906. The annual report of the medical officer of the county of Ross and Cromarty goes to show that, supported by H.M. Inspector of schools, he is drawing the attention of school boards to such defects as exist. When cases of failure of school boards to act on the recommendations of the sanitary officials are brought to the notice of the Local Government Board it is the Board's practice to coöperate with the Scotch Education Department in securing improvements in the sanitary conditions of schools.

Colwyn Bay Drainage.

In answer to Mr. Weir, Mr. Burns stated that he was informed that the whole of the drainage of Colwyn Bay had been linked up with the new drainage system and that the old sewer outfalls had been done away with.

The Royal Commission on Sewage Disposal.

Mr. Thomasson asked the President of the Local Government Board whether the Royal Commission on Sewage Disposal, appointed on May 7th, 1898, was still sitting; if so, whether he could inform the House when it would issue its report on the bacterial or artificial methods of sewage treatment as distinguished from the natural method or land treatment; and when the final report would be issued.—Mr. Burns said: The Royal Commission is still sitting, and I understand that in its fifth report, which it hopes to issue before the end of the year, the methods of sewage treatment referred to in the question will be dealt with. I further understand that the investigation of the disposal of trade effluents when not mixed with sewage, which will to him would entail. His colleagues suggested that he should hold both and so solved that difficulty for him. Professor Marsh, in a witty speech, proposed "The Visitors," which was replied to briefly by Sir Hector Cameron for Glasgow who pointed out how glad they all were to have Dr. MacAlister as their principal, and that this was an experiment as previous principals had all been divines. Sir Robert Ball replied for the Cambridge visitors and spoke of the well-known facility which Dr. MacAlister possessed for the assimilation of foreign languages. Professor Bradbury, Professor Woodhead, and Dr. Shore also spoke briefly.

The Coal Smoke Abatement Society.—The report of this society for the year 1906 states that evidence is not wanting to show that the influence of the society is now far greater than has been the case during any previous period of its existence and that many manufacturers now regard the society as a friend rather than an enemy. Amongst the authorities of which the society has most cause to complain are mentioned the West Ham corporation and the Chiswick urban district council. The society has also reported a number of nuisances in connexion with Government factories but it appears that while private manufacturers can be compelled to adopt precautions for preventing the emission of black smoke the property of the Crown is for this purpose exempt from the operation of the Public Health Acts. The promoters of several electric power and supply Bills in Parliament have asked to be exempted from proceedings for nuisances, including nuisances caused by the emission of black smoke, but the society is confident that Parliament will hesitate to clothe the proprietors of electric generating stations with such exceptional powers, especially as it is stated that certain of them have been among the worst offenders in the metropolis. Evidence shows that the emission of black smoke from factory chimneys is very largely the result of inefficient stoking. Consequently the society has established courses of instruction in stoking at the Borough Polytechnic Institute and 90 stokers availed themselves of the opportunity to perfect themselves in their work. During the year 1906 1423 cases of smoke pollution were reported by the society's inspector and 1246 complaints were forwarded by the society to local authorities. During the year the society tested 47 grates and 32 gas stoves and the reports of the tests were published in THE LANCET. Finally, the society has made tests of "Coalite," a new patented fuel which is the invention of Mr. Thomas Parker, C.E., M.I.C.E. It is claimed to be ordinary bituminous coal treated in such a manner that the smoke-producing elements are completely extracted from it without impairing its value as a fuel. The results of these tests will be published shortly. The committee appeals for subscriptions to enable it to continue its useful work without the constant strain involved in endeavouring to meet the imperative expenditure with an income of less than £300 per annum. Subscriptions may be of any amount from 5*s.* per annum and should be forwarded to the secretary, Mr. Lawrence W. Chubb, 25, Victoria-street, Westminster, S.W.

West London Hospital and Post-Graduate College.—The annual dinner of the friends of this hospital, comprising the past and present medical staffs (honorary and resident), the post-graduate students, and the lay supporters of the charity, took place at the Trocadero Restaurant on June 12th, under the chairmanship of Mr. E. Lloyd-Williams, dental surgeon to the hospital. The dinner was throughout marked with the enthusiasm born of success. After the chairman had given the loyal toasts Dr. J. Barry Ball proposed in an amusing speech "The Imperial Forces." This having been responded to by Surgeon-General W. J. Charlton, A.M.S., the Chairman proposed the toast of the evening, "The West London Hospital," in the course of which he referred sympathetically to the recent severe illness of the Duke of Abercorn, the Chairman of the Board, but was able to announce that the distinguished invalid was progressing favourably. The toast was replied to by Mr. G. F. Marshall for the Board, by Mr. C. R. B. Keetley for the staff, and by Mr. E. M. Niall for the residents. Mr. Keetley was humorous and breezy as usual and protested against the indebtedness of the hospital being regarded in any way as a bogey, inasmuch as in his experience the hospital progressed under the stress of poverty and its accompanying strain and efforts. Lieutenant-Colonel A. W. Alcock, I.M.S., then proposed "The Post-Graduate College," from whose teachings he said a large number of his brother officers had derived the greatest possible benefit and he paid the management of the college high compliments on both the manner and the matter of the instruction given. To this toast the Dean of the College, Mr. L. A. Bidwell, replied with a statement showing the progressive prosperity of the institution and its cosmopolitan character, adding that the rivalry of other and newer post-graduate schools, so far from damaging the West London Post-Graduate College, appeared to stimulate men to join the older establishment. The toast of "The Visitors" was proposed by Dr. Donald W. C. Hood and responded to by Sir Richard Douglas Powell, Bart. The Chairman's health was then proposed by Mr. Stephen Paget, when a few words from Mr. Lloyd-Williams brought the proceedings to a close. Between the speeches Mr. Wilfred Pepper and Mr. Vernon Taylor gave a well-chosen selection of ballads.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Butter and Margarine Bill.

THE Butter and Margarine Bill has passed through Committee and has been reported to the House of Commons with amendments.

Teaching Hygiene in Schools.

A petition signed by nearly 200 Members of Parliament has been presented to Mr. McKenna, President of the Board of Education, supporting the appeal of medical practitioners that instruction in hygiene and temperance in public elementary schools should be specifically introduced into the curriculum of the code. Mr. McKenna on June 6th received a deputation headed by Lord Strathcona which urged this matter on his attention and also the establishment of a medical bureau in the Education Department. The right honourable gentleman, in reply, expressed sympathy with the views of the deputation. He pointed out, however, that until the Bill which contained provisions dealing with the medical inspection of school children had become law he could not declare the settled policy of the Board of Education on the subject.

Deaths from Tetanus in the Punjab.

The return moved for by Sir William Collins of papers containing the results of an inquiry into the origin of certain deaths from tetanus in the Punjab consequent on the employment of Mr. Haffkine's prophylactic against plague has been presented to Parliament.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 5TH.

The Wincanton Hospital District.

Mr. J. W. H. Thompson asked the President of the Local Government Board whether an order of the Local Government Board had been made, after inquiry held, whereby the rural district of Wincanton, Somerset, had been constituted a hospital district and an isolation hospital established; whether there were any other purely rural districts in which such a hospital had been permanently provided; whether he was aware that the almost unanimous feeling in the district was opposed to the establishment of a permanent hospital; and whether, in view of the evidence in opposition offered at the inquiry, he was prepared to reconsider this order.—Mr. Burns answered: An appeal was made to the Local Government Board against an order of the Somersetshire county council constituting the Wincanton rural district a hospital district under the Isolation Hospitals Acts. The Board after local inquiry issued an order dismissing the appeal and I cannot reopen the matter now. There have been several cases in which rural districts have been constituted hospital districts under the Isolation Hospitals Acts and many more in which permanent hospitals for infectious disease have been established in such districts under the Public Health Acts.

The Health of Miners.

Mr. Cochrane asked the Secretary of State for the Home Department whether the report and evidence of the Royal Commission which had been considering the health and safety of miners could be laid upon the table forthwith in order to prevent the delay which would occur owing to the decision of the Government that the scope of the Commission should be enlarged by reporting upon accidents in quarries.—Mr. Gladstone replied: The first report of the Commission, which deals with the use of breathing appliances, will be presented to Parliament this week and I am informed that the first volume of evidence is likely to be ready next week. A large number of questions connected with coal mines upon which evidence is now being taken remain to be dealt with by the Commission, and I understand that it intends to present its report upon these before proceeding to that part of the inquiry which relates to quarries.

The Treatment of Inebriates in London.

Mr. Pickersgill asked the Secretary of State for the Home Department whether his attention had been drawn to the fact that the London County Council had determined to terminate the arrangement which it entered into in 1904 with the National Institution for Inebriates, under which inebriates committed from London were sent to the latter's reformatories on condition that the more hopeful class of cases should be transferred to the Council's reformatory at Farmfield; whether the effect of this decision would be that London magistrates would be deprived of the opportunity of committing inebriates to inebriate reformatories, except as regarded a small number of strictly selected cases eligible for Farmfield; and what steps he proposed to take to render possible the continued committal set out in the memorandum, but I think I must draw the line at other objects, however desirable, for which your society may wish to see legislation passed.

Dr. HERON: May I then take the clauses of the Bill as they stand? He went on to say that his society thought that, although it was very desirable that joint-stock companies should be dealt with in the way proposed in the Bill, in embracing joint stock companies alone the scope of the measure was unduly limited. In this way many of the companies now practising would escape. They thought the Bill might be so amended as to bring these companies within its scope.

The CHAIRMAN: What are these other companies to which you allude?

Dr. HERON: Companies which are not joint-stock companies.

The CHAIRMAN: Within your own knowledge are such companies in existence?

Dr. HERON: Yes. We think it would be very easy for companies dealt with under this Bill to drop the words "joint-stock companies" and so put themselves outside the scope of the Bill.

The CHAIRMAN: I see your point.

Dr. HERON further said that one of the subsections of Clause I. of the Prohibition of Medical Practice by Companies Bill laid down that anything that would be an offence under the Medical Acts if committed by an individual should be an offence if committed by a company. His society found it very difficult to work the Medical Acts with a view to preventing malpractices. The Medical Acts hit very few men who did not pretend to be legally qualified. They dealt very effectively with the man who pretended to be legally qualified when he was not. He would suggest something should be added to make the scope of the Bill wider and to bring into its scope men who were unqualified.

The CHAIRMAN: I doubt if that is not a different object from that of the Bill. Do you come to tell us that there are a great many illegalities going on around us by unqualified men?

Dr. HERON: What I come here to say is that we accept this Bill with pleasure but we hope it is in the power of your lordships' committee to make the Bill a little more effective than it is.

The CHAIRMAN: Are you friendly to the lines the General Medical Council is taking?

Dr. HERON: Certainly. He further said that the British Medical Association requested his society to send a witness to give evidence before the committee.

Dr. A. G. BATEMAN, general secretary to the Medical Defence Union, then gave evidence. After giving some particulars as to the work of the Medical Defence Union he said that in the past 20 years they had prosecuted about 200 unqualified practitioners. The difficulties which they found in dealing with these unqualified practitioners were many. One of these difficulties would undoubtedly be got rid of if the Bill prohibiting practice by joint-stock companies was passed. That difficulty, however, was a minor one. Although there were a certain number of companies practising medicine under the protection of the Companies Act there were a much larger number of companies which were practising medicine and which were not under the Companies Act but which were equally immune from prosecution. There were literally hundreds of companies which would not be hit by the Bill. For one company of this kind under the Limited Liability Companies Act there would be 20 or 30 perhaps not under these conditions. He had a strong suspicion that malpractices, like the procuring of abortion, were carried out at some of the places at which these companies carried on business. However, no definite evidence could be obtained and therefore action could not be taken. His point was this, that although the Bill would have a good effect so far as it went it would only apply to companies under the Joint Stock Companies Acts.

The CHAIRMAN asked what amendments the Medical Defence Union had to suggest with respect to the Bill.

Dr. BATEMAN: The amendment we would like to the Bill would be a complete alteration of the title and a complete alteration of the clauses, so as to put a stop to medical practice for gain by persons who are not qualified. I am afraid that nothing else would be effectual. I am afraid that this Bill will have a very slight effect.

The CHAIRMAN: You say then that this Bill will do very little.

Dr. BATEMAN: I think it will have very little effect. These joint-stock medical companies will liquidate and will then become more or less private companies immune from prosecution. They cannot be touched by the Medical Acts, the Companies Acts, or by this Bill.

The CHAIRMAN: I am afraid, then, that this Bill has very few friends.

Dr. BATEMAN proceeded to state that the practice of some of these companies was not confined to the poor by any means. In one case which he had come across he had found that even general officers in the army had come forward to support what was nothing less than a fraud.

Mr. R. D. PEDLEY, who appeared as a witness from the London and Counties Medical Protection Society, strongly urged the suppression of dental companies.

Mr. H. ROWLAND BLUNT, who described himself as appearing on behalf of the National Association of Medical Herbalists, asked permission from the committee to tender evidence, on the ground that the Medical Bill would prevent that organisation from being carried on under the Companies Acts. He stated that the association was composed of medical herbalists for mutual protection. It had between 200 and 300 members.

The CHAIRMAN: Will you describe generally what your work consists of?

Mr. BLUNT: It is treating patients with herbal remedies who come to the shop or place of business.

The CHAIRMAN: Do you say your members have a large practice?

Mr. BLUNT: Some of our members have very fair practices.

The CHAIRMAN: An increasing practice?

Mr. BLUNT: I think I can safely say so.

The CHAIRMAN: Medical herbalists are generally what is known as unqualified men?

Mr. BLUNT: Unregistered men.

The CHAIRMAN: We have heard the word "unqualified" used.

Mr. BLUNT: Unregistered is a better word, your lordship.

The CHAIRMAN: But do you recover fees?

Mr. BLUNT: No, not fees for advice, but we recover for goods supplied.

Lord LUDLOW: Do you call yourselves physicians?

Mr. BLUNT: No.

Lord LUDLOW: Surgeons, then?

Mr. BLUNT: No.

Lord LUDLOW: Medical practitioners?

Mr. BLUNT: Yes. Medical practitioners with herbal remedies.

Lord LUDLOW: Could you come here and say, "I am a medical practitioner and therefore I protest against the Bill?"

Mr. BLUNT: No. I do not. Further, he could not claim, when pressed by members of the committee, that medical herbalists were qualified practitioners.

The committee finally decided that it would not hear Mr. Blunt as a witness on the details of the Bill.

Mr. VICTOR GOODMAN gave evidence in which he expressed views contrary to provisions of the Bill dealing with dental companies. He was of opinion that the Bill would be unjust to men who might have been removed from the Register on a mere question of etiquette. He contended that it was never intended that removal from the Register should altogether prevent a man from getting his living. He also stated that it was quite possible to supply teeth for a guinea a set.

Mr. L. CALLENDER, who stated that he belonged to the Amalgamated Association of Mechanical Dentists, also appeared as a witness. He had sold thousands of sets of teeth at a cheap rate and he maintained that the surgical and mechanical departments of dentistry were distinct. He never allowed his staff to interfere with people who required surgical aid. He maintained that the Bill would be unjust to the class which he represented.

The committee at this point adjourned until Monday, June 10th.

On Monday, June 10th, the Select Committee of the House of Lords resumed the hearing of witnesses on the Prohibition of Medical Practice by Companies Bill and the Dental Companies (Restrictions of Practice) Bill, Lord HYLTON again presiding.

Mr. G. S. BARNES, Controller of the Companies Department of the Board of Trade, was the first witness. He spoke at some length of the difficulties which the Board had experienced in dealing with the registration of dental companies in view of conflicting legal decisions and opinions. However, in 1905, they had asked the English, Irish, and Scottish law officers of the Crown to meet in consultation and frame an opinion to guide the Board. They met and gave their opinion in the following terms:—

"We recommend that if the title of the proposed company contains the word 'dentist' or any expression calculated to lead the public to suppose that the company is specially qualified for the purposes of dentistry, registration should be refused, even if one or more of the signatories to the memorandum of association are persons duly qualified to practise dentistry. When the title of the company is not misleading we think the registration should be granted, although the company is formed to carry on the business of a dentist. If the company, after being formed, advertises itself as dentists or dental surgeons the question whether any liability is thereby incurred must depend on the view ultimately taken on the construction of the Dentists Act. The possibility of such an abuse is in our opinion no reason for refusing the registration."

The CHAIRMAN: Would you suggest that the words "joint stock" should be struck out of the Dental Bill so as to throw the net as wide as possible?

Mr. BARNES: I think it would be well to spread the net as wide as possible.

Lord KNUTSFORD: If a company were formed abroad that would strike at it?

Mr. BARNES: Yes.

The CHAIRMAN: The scope of the Bill includes companies registered in "the British Islands." I think that these words were introduced to include the Channel Islands and the Isle of Man. Would the term "United Kingdom" include the Channel Islands?

Mr. BARNES: I do not think so.

The CHAIRMAN: Would the words "British Islands" include the Channel Islands?

Mr. BARNES: I think so.

The CHAIRMAN: Are the Channel Islands in the British Islands?

Mr. BARNES: They are a fief of the Dukedom of Normandy.

The CHAIRMAN: But is the law carried out as under the Duke of Normandy now?

Mr. BARNES: I think it is carried out under the old *coûtume de Normandie.* The witness admitted that it had been the custom of companies to register outside the United Kingdom to evade the Companies Acts.

Mr. JAMES V. ALBERT was also examined as a witness. He said that frequently patients had been improperly treated by so-called dental companies. He gave it as his opinion that the mechanical and surgical parts of the dental profession could not properly be treated as separate. He did not want to see company practice recognised in dentistry.

Mr. BOWEN (Bolton), who has been a teeth extractor for many years and the managing director of a company carrying on a teeth business, also gave evidence. He admitted that he was not a qualified dentist, but he had gained experience in extracting teeth under the supervision of his father who was a medical man. He objected to the Dental Bill which would interfere with his business. It would give a monopoly to less reputable practitioners—the men who got into the dental profession in 1878. Many of them had not the training which many unregistered men had.

The CHAIRMAN: Mr. Bowen, I do not think you will make much of a point by attacking the Dentists Act of 1878. We cannot hear evidence on that. You had better confine your observations against the Bill to the way in which it will affect the public.

Mr. BOWEN argued that some dental companies met a public want. The men who would benefit from the Bill would be the men who obtained their registration from the fact that they were in practice before 1878. They would bring things into a worse state than ever. Dentists who held an L.D.S. would not be allowed by the institutions from which they got their diploma to take service with companies. The only persons to accept these terms would be the registered men who came into the Register before 1878.

Mr. FITZROY, of the Privy Council, appeared to give evidence of its views on the Bills. It was, he said, only owing to recourse being had to the Companies Acts that any considerable practice by unqualified persons of dentistry had come to be possible. The Privy Council had always held that no individual could profess to practise dentistry unless he was properly qualified.

Lord KNUTSFORD: We have been told that there is a great difficulty in separating the mechanical side of dentistry from the surgical.

form the subject of the final report of the Commission, has been commenced.

American Tinned Meat.

Captain FABER asked the President of the Board of Trade whether he had any official information showing that a report had been published by the State Commissioner of Health at Albany to the effect that the reforms to be made in American tinned meat were still incomplete, and that the chemical analyses on 154 samples of canned meats showed the presence of boron preservative and other bad matter; and, if so, whether he would take steps to prevent these canned meats being landed in England.—Mr. BURNS (who replied) said: I have seen an account in a newspaper of the report referred to in the question. It does not appear to me that in the present state of the law I am empowered to take action of the kind suggested by the honourable Member; but as he is no doubt aware, I have before the House a Bill which would empower me to make regulations authorising measures to be taken for the prevention of danger to the public health arising from the importation of articles of food.

TUESDAY, JUNE 11TH.

Combating the Plague.

Dr. RUTHERFORD asked the Secretary of State for India whether he had yet received answers to his questions addressed to the Government of India relating to the numbers of medical men engaged in combating the plague.—Mr. MORLEY replied: I have not yet received the return. The figures may take some little time to collect.

Deaths from Plague.

Dr. RUTHERFORD asked the Secretary of State for India whether he would give the House the weekly returns of deaths from plague during May for each province in India.—Mr. MORLEY answered: The deaths returned for the weeks ending May 4th, 11th, and 18th respectively are for all India 77,772, 82,400, and 67,512. Later figures have not yet been received. I shall be very willing to communicate the provincial returns for those weeks to the honourable Member or to place them in the library.

The Administration of the Vaccination Act.

Sir WILLIAM COLLINS asked the President of the Local Government Board whether he was aware that, by general orders of Oct. 31st, 1874, the Local Government Board prescribed it as the duty of the guardians of the poor to give directions to their vaccination officers to take proceedings in cases in which the proceedings of the Vaccination Act of 1867 had not been complied with, and that in July, 1875, the Local Government Board obtained a mandamus to compel the guardians of the Keighley union to give directions to their vaccination officer; and that in consequence of their default the guardians of that union suffered imprisonment; whether, seeing that Lord Herschell's Commission on Vaccination reported in 1896 that it was the duty of the guardians to put the law in regard to vaccination in operation, he would say whether the powers and duties of guardians in regard to such prosecutions under Sections 29 and 31 of the Act of 1867 had since been altered by statute; and, if not, whether the powers of the guardians in directing their officers in instituting proceedings under the Vaccination Acts were the same now as they were held to be in 1875 and in 1896.—Mr. BURNS sent a written reply in the following terms: I am aware of the facts referred to in the question. Some limitations were placed by Sections 2, 3, and 4 of the Vaccination Act, 1898, on the cases in which prosecutions could be instituted under Sections 29 and 31 of the Vaccination Act, 1867, but, subject to this, there has been no statutory provision since 1896 which would affect the powers and duties of guardians in regard to prosecutions under those sections. Since that date, however, the courts of law have decided that it is the duty of the vaccination officer to institute these prosecutions without any directions from the guardians. When in 1898 the Order of 1874 mentioned by my honourable friend was rescinded, the provision which it contained as to directions by the guardians in cases of this kind was not inserted in the Order which took its place. That Order provided, however, that the guardians should from time to time ascertain whether the vaccination officer was performing the duties imposed on him by the Vaccination Acts of enforcing the provisions of those Acts and the duties imposed on him by the Order, and should require the due performance by him of such duties.

WEDNESDAY, JUNE 12TH.

Women Sanitary Inspectors.

Mr. COOPER asked the President of the Local Government Board, whether he could state how many women had passed during the last ten years the examination required to qualify for a sanitary inspector; and how many sanitary authorities had appointed a female sanitary inspector on their staff.—Mr. BURNS replied (by written answer): It is only in London that a sanitary inspector is required by law to be the holder of a certificate granted by a body approved by the Local Government Board to the effect that he has by examination shown himself competent for such office. I understand that the number of women who have passed the qualifying examination during the ten years ended 31st December last is about 216, and that the number of metropolitan borough councils who have appointed one or more female sanitary inspectors is 22.

MEDICAL AND DENTAL COMPANIES: EVIDENCE BEFORE A SELECT COMMITTEE.

A Select Committee of the House of Lords, presided over by Lord HYLTON, heard further evidence on June 6th in connexion with the Prohibition of Medical Practice by Companies Bill and Dental Companies (Restriction of Practice) Bill.

Mr. R. W. TURNER, counsel to the British Dental Association, was the first witness. He stated that he had been about 15 years counsel to this association and had also on behalf of the British Medical Association and Medical Defence Union had to consider proposals for the amendments of the Medical and Dentists Acts. His experience of these Acts was that very considerable ingenuity was shown in evading them. The views of the British Dental Association were, of course, that company practice in dentistry should be absolutely prohibited. The public suffered from company practice as well as the dental profession. Enormous fees were sometimes charged by these companies—twice or three times as much as a first-class dentist would charge. However, he had considered the Dental Bill with a view to finding out whether, and how, it could be evaded. He would, in the first place, suggest that companies, if allowed to practise at all, should only practise by means of registered dentists, and, further, that no new companies should be allowed to be formed for the practice of dentistry. He submitted a number of specific amendments with a view to strengthening the Bill. He pointed out that the word "company," as used in the Bill, would not prevent a foreign company, or one registered in the Channel Islands, or the colonies, from carrying on by means of agencies the business of dentistry and thereby successfully evading the proposed Bill. These difficulties would be got over by defining a company under the Bill as "any association, whether incorporated or unincorporated, within or without the United Kingdom." He would extend the liability to answer for a contravention of the law to all persons who were engaged at the place where the contravention occurred in the practice of dentistry on behalf of a company. Mr. Turner further pointed out that the penal clause of the Dentists Act had received a more limited interpretation in Scotland than in England or Ireland. In Scotland it was not an offence for an unregistered man to use the description dental surgery. In England and Ireland this was an offence. In other words, the Scotch courts had decided that the words "style, title, or description" were limited to words of personal description and not to words descriptive of premises or practice. The effect of this decision was to afford an easy means of evading the Act in Scotland. This was shown by the fact that in the return of companies practising dentistry made in 1904 there were 70 in England and Wales and 22 in Ireland and only three in Scotland. In order to deal with this anomaly he would submit that a subsection should be introduced into the Bill to provide that the words "title addition or description" where used in the Dentists Act, 1878, should include "any words or letters implying that the practice of dentistry is being carried on." He further pointed out that there were omissions from the Bill in the attempt to penalise the company *quâ* company. The first point had reference to the serving of the summons. Under the Summary Jurisdiction Acts a summons must be served by post at the registered office of the company. There was no machinery whereby this could be effected if the registered office were in Ireland and the offence were committed at a branch office in England and *vice versâ*. There was a machinery as between England and Scotland but it was complicated. He therefore suggested that the summons could legally be served at any office or place of business of the company within the jurisdiction of the court in which the proceeding was brought. There was a further difficulty with regard to the recovery of penalty and costs. In the case of an individual imprisonment followed in default of distress. This was impossible in the case of a company and there was no process whereby a company *quâ* company could be forced to pay if there was not sufficient distress. Goods and materials could all be covered (1) by a debenture; (2) by a hiring agreement; (3) by a bill of sale; and (4) by being the property of the practitioner or some other person. He would therefore suggest that to make the Act effective the following provision should be inserted: "The court shall, when a registered company is fined, direct that the fine and costs shall be paid by the company by a date not later than one month from the date of conviction and if the fine and costs are not paid by that date the court shall forthwith send a certificate of such conviction to the Registrar of Joint Stock Companies where the company is registered and the Registrar shall forthwith strike such company off the Register." Mr. Turner further thought that it would be desirable to add a clause that a person should not be entitled to recover for any work done or materials provided unless he was registered under the Dentists Act. He did not know whether it would be possible to make a provision whereby any person on the relation of the law officers of the Crown could take proceedings by way of injunction or interdict against a company carrying on business in contravention of the Act. A company was so elusive that he believed some such clause as this would do more than anything else to prevent an evasion of the Act. If it were inserted the need for invoking the penal clauses would be diminished and foreign companies could be got at effectively in this country, so far as their agencies were concerned. The difficulties that he had referred to with regard to the recovering of fines also applied to recovering damages and costs for malpraxis. The unfortunate patient would probably get nothing. He knew of such cases within his own experience. The practitioner vanished and he could not be brought before the General Medical Council. The security that the patient got by having the individual responsibility of the practitioner was lost when the company appeared on the scene. And when an action for damages lay it was discovered that the company, being a corporation, had neither cash nor conscience.

Lord LUDLOW: Assuming that this Bill passes into law, qualified dentists can form a company. Do you see any objection to that?

Mr. TURNER: I do see objections to it. Take a company formed of seven qualified men. There is nothing in the Bill which would cause them to do anything else than to employ some registered practitioner and get him to carry on a practice on their behalf. You at once have this registered man employed. What is the object? Gain. You at once lose the relation of practitioner to patient. He at once says: "I must make money for my employers." Assuming that he is guilty of malpractices the company gets rid of him. He goes elsewhere and another man is put in his place. The company continues. A judgment is got against the company. These registered people perhaps have given some outside person a debenture over the company's assets. Then nothing can be got. In the case of an individual professional man a personal relationship exists. Any other arrangement would lead to avoiding the liability.

Dr. G. A. HERON, chairman of council of the London and Counties Medical Protection Society, was the next witness. He stated, in answer to the CHAIRMAN, that the Prohibition of Medical Practice by Companies Bill had been considered by the committee of his society. They would prefer to have the Bill passed rather than not to have it. However, they hoped that before it became an Act it might be made much more far-reaching than it was at present. For instance, they should like to see a Bill of this kind hitting at unqualified men in whatever way they might practise and in such a way as to bring them within the grasp of the law.

The CHAIRMAN: I think, Dr. Heron, it would not be within the terms of our reference to go into subjects altogether outside the scope of the Bill. What we must ask you to do is to confine yourself to the subject-matter of the Bill and the views of your society on it. Of course, you are thoroughly acquainted with the objects of the Bill as

National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury.—Senior and Junior House Physicians. Salary £50 per annum, with board and residence in each case.

New Hospital for Women, Euston road, N.W.—House Surgeons (females). Also Clinical Assistant.

Newcastle-upon-Tyne, City and County of.—Assistant Medical Officer of Health and Resident Medical Officer of the City Hospital for Infectious Diseases, unmarried. Salary £300 per annum, with board, lodging, &c.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £160.

Newport and Monmouthshire Hospital.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and laundry.

Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Salary £20, with apartments, board, and laundry.

Oldham Workhouse.—Resident Medical Officer, unmarried. Salary £150 per annum, with residence, coal, gas, rations, washing, and attendance.

Oxford, University of.—Professorship of Pathology. Income of £700 per annum from the University Chest.

Rotherham Hospital and Dispensary.—Senior House Surgeon. Salary £110 per annum, with rooms, commons, and washing.

Royal Free Hospital, Gray's Inn road, W.C.—Junior Obstetric Assistant for six months, with board, lodging, and laundry. Also Clinical Assistants (all females). Also Assistant to the Clinical Pathologist (female). Salary £50 per annum.

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £40 per annum, with board and washing.

Salisbury Infirmary.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, and lodging.

Sanitary Inspectors' Examination Board.—Examiner.

Seamen's Hospital Society, Greenwich.—Assistant Ophthalmic Surgeon to the "Dreadnought" Hospital.

Sheffield Fever Hospitals.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

Sheffield, University of.—Demonstrator in Physiology. Salary £150 per annum.

Taunton, Taunton and Somerset Hospital.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

University of London (University College).—Assistant in the Anatomical Department and Curator of the Anatomical Museum.

Wallasey Dispensary and Victoria Central Hospital.—House Surgeon, unmarried. Salary £100 per annum, with apartments, board and service.

West Bromwich District Hospital.—Senior House Surgeon, unmarried. Salary £110 per annum, with, board residence, and laundry. Also Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and laundry.

West London Hospital, Hammersmith road, W.—Officer in Charge of X Ray Department.

Western General Dispensary, Marylebone-road, N.W.—Senior House Surgeon. Salary at rate of £100 per annum, with board, residence, and washing.

Worcester General Infirmary.—House Physician. Salary £50 per annum, with board, residence, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Louth, in the county of Lincoln, at Lochwinnock, in the county of Renfrew; and at Whitby, in the county of Yorks.

Births, Marriages, and Deaths.

MARRIAGES.

Arnison—Trustram.—On the 8th June, at St. Paul's Church, Avenue road, N.W., by the Rev. H. Bury, William Drewett Arnison, M.D. the eldest son of the late George Arnison of Allendale, Northumberland, to Christine Mary, youngest daughter of the late William Prince Trustram and Mrs. Trustram, of Lauderdale Mansions, Maida Vale.

Braddon—Josling.—On June 6th, at Holy Trinity Church, Upper Tooting, William Vaudrey Braddon, M.B.Cantab., to Beatrice, second daughter of the late George Frederick Josling, Great Thurlow Hall, Suffolk, and Mrs. Josling, of Kinnoull, Tooting Common, S.W.

Cole—White.—On the 11th June, at the Church of the Annunciation, Bryanston-street, W., by the Rev. Prebendary C. M. Harvey, Vicar of Hillingdon, assisted by the Rev. Canon E. B. Ottley, Vicar of the parish, Robert Henry Cole, M.D., of 25, Upper Berkeley street, Portman-square, to Mabel Effie, widow of Arthur Thomas White, M.R.C.S., of the Egyptian Public Health Service.

Sanders—Brandon.—On June 12th, at St. Stephen's Church, Ealing, by the Rev. Eyton-Jones, Edward Arthur Sanders, of Northampton, younger son of Lieutenant Colonel E. Sanders, to Ruby Ethel Ruth, fourth daughter of the late Henry Brandon of Queensland, and Mrs. Brandon, of 4, Kent Gardens, Ealing.

DEATH.

Gill.—On June 11th, at Pembury-road, Clapton, Samuel Lawrence Gill, M.R.C.S., L.R.C.P., within seven days of his 84th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"THE CHEMICALISED ROAD."

With reference to our annotation under the above heading in The Lancet of May 25th, p. 1443, the managing director of the Akonia Syndicate, Limited, of 120-122, Birkbeck Bank Chambers, High Holborn, London, W.C., states that their "dust layer" known as akonia, the application of which is based upon its hygroscopic properties, has been used in some hundreds of towns in England and Wales since 1903, and up to the present "not a single complaint has been received of any unpleasant results either to tyres or clothes." It is stated that the preparation is odourless, and that if by chance it was spread on clothing a simple application of clean water would remove all effects. The preparation being clean compares favourably with tar and mixtures of oil and is said to have the advantage over tar and oil mixtures that it does not encourage side slip. Reports are quoted in which very favourable opinions are given as to the effectual way in which akonia suppresses dust. The point which we raised was whether it would not be found that chemical salts in the long run would lead to the formation of irregularities in the surfaces of roads or prove destructive to tyres, metal work, boots, or the hoofs of horses and cattle. Common salt, it is true, is a neutral substance, but everybody is familiar with its corrosive action on metal fittings, leather, and so forth. Calcium chloride, even when neutral, acts in a similar way owing to the dissociation of its "ions" calcium and chlorine when dissolved in water.

THE MEDICAL PROVISION ON SMALL LINERS.

To the Editors of The Lancet.

Sirs,—When a medical man advises a patient to take a sea voyage he does not always pay sufficient attention, I think, as to the quality of medical provision on the particular vessel selected. This may be of grave importance to the traveller; I have seen instances of this on the many voyages it has been my lot to take as an ordinary passenger. Ship surgeons vary very considerably even on British liners, though, speaking generally, those on the big British lines are superior to those on the continental. The worst of all are the men on the Japanese passenger steamers. According to my experience, any voyager to the East likely at all on the journey to need medical assistance cannot do better than patronise the P. & O. boats. The surgeries on these liners are admirably fitted up, the supply of drugs adequate, and the surgeons as good, if not better, than any to be found on the sea. On some foreign boats, where things are run on the cheap and the passage money low, the so-called "qualified" surgeon and the medicines at his disposal are alike very poor. Invalids are running a grave risk who submit to be at the mercy of an incompetent man when far away at sea and with no other help at hand.

I am, Sirs, yours faithfully,
Nanning Fu, China, May 1st, 1907. H. Lechmere Clift.

AN ILLUSTRATION OF HOW CONSUMPTION IS SPREAD.

At Poplar recently Mr. Wynne Baxter held an inquest upon the body of a labourer who was proved by medical evidence to have died from consumption. It was also proved that the wife of the deceased had died only two months earlier from the same disease and that upon her also an inquest was held. The medical witness pointed out to the jury that the husband had probably been infected by his wife, but it is to the fact of an inquest having been held in both cases that the attention of the public should also be drawn. The inquests must have been rendered necessary owing to neither the husband nor the wife having sought medical aid, and their not having done so even when dying illustrates the difficulties which beset those who would diminish the spread of the disease which proved fatal to them.

THE ANTIVIVISECTIONIST AT LARGE.

In the latter part of the month of April a meeting was held at Malvern with a view to form a Malvern branch of the National Antivivisection Society. The chairman was Mr. H. A. Acworth. The lecturer was Mr. Sommerville Wood, the official lecturer of the society, and among the audience was Viscount Harberton. Mr. Sommerville Wood mentioned that Mr. O. C. Duncan, the Worcestershire county analyst, held a licence for vivisection, that the licensed place was Shuttlefast farm, Malvern, and that 21 experiments had been conducted by him under one licence and six under the other. Viscount Harberton then wrote to the Malvern Advertiser saying that he considered that Mr. Duncan had "taken out a licence to do what he regards to be justifiable but which we, on the other hand, regard as wicked and cruel." The chairman of the Worcestershire county council, Mr. Willis Bund, then wrote to the Malvern papers pointing out that it was quite true that Mr. Duncan did hold a vivisection licence, but that the only experiments at Shuttlefast farm were placing live fish in the different effluents from the sewage farm to see how and to what degree they were affected by it. Lord Harberton therefore wrote to the Malvern Advertiser to say that as regards what was done at Shuttlefast farm Mr. Duncan could not be considered a vivisector.

Mr. FitzRoy: I agree it is impossible to make the distinction and therefore the practice of unqualified persons should be eliminated.

Lord Knutsford: You would also agree that the great majority of companies do not take the care to differentiate between the surgical and the mechanical work?

Mr. FitzRoy: I should say so. The lack of skill disqualifies the subordinate from observing any instructions he has not to undertake the surgical work.

Lord Knutsford: The Privy Council, I understand, approves of these Bills as they stand. Would it prefer stronger measures?

Mr. FitzRoy: I think the Privy Council on the whole approves of them as they stand. I think it would be difficult to refuse the right to practise dentistry through properly qualified men to properly constituted companies.

Mr. F. W. **Bradley**, of F. W. Bradley, Limited, which carries on artificial teeth work in East Anglia, was then examined. He said that when he was studying pharmacy he also studied dentistry. In consequence of his business having grown to a great extent he registered it under the Joint Stock Companies Acts. He had employed assistants, some registered and others unregistered.

The **Chairman**: You hold that the company F. W. Bradley, Limited, is a source of benefit to the public?

Mr. Bradley: I have a great deal of evidence to prove that it has been of benefit in East Anglia. He went on to say that it met a demand. It used the words "artificial teeth manufacturers" as a description. The Dental Bill before the committee would if it became law prevent it from practising dentistry. That would be absolute ruin to him.

The **Chairman**: In the interest of the public, which we must consider more than anything else in this legislation, you think your company has been of benefit by the lower charges it makes?

Mr. Bradley: I think so undoubtedly.

The **Chairman**: Now supposing the Bill becomes law, would there be great difficulty in getting qualified assistants? Is there a greater difficulty in getting qualified assistants than getting unqualified?

Mr. Bradley: There is a great difficulty in getting registered men. The young men have the L D.S. and they prefer to work on their own account. He had himself found a great difficulty in getting qualified men. Hence he employed unregistered men. Such registered men as were available were often incompetent.

Lord Knutsford: You will admit that there are a great many bogus companies doing a great deal of mischief?

Mr. Bradley: Yes, my lord.

Lord Knutsford: That is the case we have to meet. Now, do you think there are some working companies which can prove that they are doing a *bonâ-fide* business? If we exempt them your difficulty would be met?

Mr. Bradley: Yes, that would meet my views and the views of those who are carrying on *bonâ-fide* businesses.

Lord Knutsford: So far as we have seen some companies have been able to act for the benefit of the public. If they can prove that they should be exempted from the Bill. Now is that your view?

Mr. Bradley: Yes, my lord.

Mr. **Doweswell**, representing the Macdonald Manufacturing Company, also gave his views on the Dental Bill. The registered offices of his company had always been in London. They did not offer medical advice.

The **Chairman**: Do you practise dentistry?

Mr. Doweswell: Only that part of it which is incidental to the adaptation of artificial teeth.

The **Chairman**: I should have thought that the adaptation of artificial teeth was incidental to dentistry. You have put it foremost.

Mr. Doweswell: Yes, my lord.

The **Chairman**: There has been something said about qualified assistants. What are your experiences?

Mr. Doweswell: There has been great difficulty in getting qualified assistants. We can only get the men registered in 1878. The conditions under which the licentiates in dental surgery obtain their qualifications prohibit them from accepting service with an advertising company.

The **Chairman** put it to the witness that companies put on the prices to earn dividends.
